Foreword

This edition of the U.S. Geological Survey (USGS) Minerals Yearbook discusses the performance of the worldwide minerals and materials industries during 2000 and provides background information to assist in interpreting that performance. Content of the individual Minerals Yearbook volumes follows:

- Volume I, Metals and Minerals, contains chapters about virtually all metallic and industrial mineral commodities important to the U.S. economy. Chapters on survey methods, summary statistics for domestic nonfuel minerals, and trends in mining and quarrying in the metals and industrial minerals industries in the United States are also included.
- Volume II, Area Reports: Domestic, contains a chapter on the mineral industry of each of the 50 States and Puerto Rico and the Administered Islands. This volume also has chapters on survey methods and summary statistics for domestic nonfuel minerals.
- Volume III, Area Reports: International, is published as four separate reports. These regional reports contain the latest available minerals data on more than 190 foreign countries and discuss the importance of minerals to the economies of these nations and the United States. Each report begins with an overview of the region's mineral industries during the year. It continues with individual country chapters that examine the mining, refining, processing, and use of minerals in each country of the region and how each country's mineral industry relates to U.S. industry. Most chapters include production tables and industry structure tables, information about Government policies and programs that affect the country's minerals industry, and an outlook section.

The USGS continually strives to improve the value of its publications to users. Constructive comments and suggestions by readers of the Minerals Yearbook are welcomed.

Acknowledgments

Volume I, Metals and Minerals, of the Minerals Yearbook presents data on more than 80 minerals and materials that were obtained as a result of the information gathering activities of the U.S. Geological Survey.

The collection, compilation, and analysis of domestic mineral industry data were performed by the staff of the Minerals Information Team. Statistical data were compiled from information supplied by mineral producers and consumers in response to canvasses, and their responses are gratefully appreciated. Information obtained from individual firms by means of the U.S. Geological Survey canvasses has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonproprietary sources or when permission of the respondent has been granted. The chapters on "Survey Methods" and "Statistical Summary" discuss in greater detail procedures for canvassing the mineral industry and the processing and evaluation of these data. Other information appearing in this volume was obtained from the trade and technical press, industry contacts, and additional sources; this cooperation is gratefully acknowledged.

Statistics on world production were compiled from numerous sources, including reports from the U.S. Department of State. U.S. foreign trade data were obtained from reports of the U.S. Department of Commerce, Bureau of the Census. The U.S. Geological Survey also was assisted by numerous cooperating State agencies.

MINERALS AND MATERIALS IN THE 20TH CENTURY—A REVIEW

By David E. Morse and Anna N. Glover

The period from 1900 to 2000 was marked by significant changes in the various industries that consume metals and industrial minerals and by major historic events that affected the way minerals are produced and used. This chapter is an overview of some of those changes. The pivotal changes to production and consumption of individual commodities are covered in the annual mineral commodity reviews in this 2000 edition of the U.S. Geological Survey's Minerals Yearbook.

The industrial revolution, which began in the late 1700s, continued through the 20th century, with the pace of technologic discovery and advancement increasing continually. The steam engine that had merely augmented wind, water, and muscle power before the advent of the 20th century gave way to diesel- and gasoline-fueled engines, which for the most part replaced older forms of energy used. The emergence of electric power and its widespread use caused an upsurge in technology that required less manpower and man-hours to complete the same tasks as were previously being done manually. The creation of the computer chip and the subsequent discoveries brought about more inventions the implementation of which facilitated the efficiency of a multitude of applications.

During the century, the Government increased its involvement in consumer protection and legislated various fields in response to activist movements. Legislation enacted by Congress through the century included civil rights, consumer protection, retirement plans, environmental protection, food and drugs, health care, labor/management relations, law enforcement, occupational safety, and social justice, as well as the New Deal, which was created to help the country's economy to grow after the Great Depression.

Experimentation and invention throughout the century in metallurgy, metals production technology, and metals forming and shaping resulted in the ability to produce metals of high purity, some alloys of high strength, others with corrosion resistance, and some with resistance to abrasion and erosion in chemically aggressive and high temperature regimes. Lightweight, low-density metals, such as aluminum and titanium, became important. Furnaces changed, refractories improved, continuous operations replaced batch processes, and electrochemical and hydrochemical processes augmented or replaced pyrometallurgical processes. In steelmaking, the basic oxygen and electric arc furnaces replaced the Bessemer and open-hearth furnaces. Glassmaking technology improvements resulted in tougher, stronger, and more brilliant glasses, and low thermal expansion borosilicate glass had improved shatter resistance. Chemical industry innovations improved mineral acid production; the lead chamber batch process for making sulfuric acid was replaced by the high-volume contact process with associated electric cogeneration plants. Lead oxide and barium/zinc-base lithopone white pigments were replaced by titanium dioxide, which improved whiteness and reduced the health hazard from heavy metal ingestion.

Systems to handle bulk materials improved greatly during the century. Salt and cement, which were routinely shipped in barrels in the early 1900s, were transferred at high rates on conveyor belts and pneumatic pipelines to covered hopper bottom dump railcars, which could haul 90 metric tons (t), and to over-the-road trailers that could move 20 to 30 t. Bulk handling facilities at ports had stacker/reclaimer systems that could move thousands of tons an hour. Open hopper railcars had specially designed couplers that allowed them to be emptied in rotary dumpers without uncoupling; belt and silo systems were used to fill unit trains, which were in continuous motion. Ocean-going bulk carriers capable of hauling hundreds of thousands of tons were in service, most with self-unloaders. Sulfur was shipped molten in special railcars and on uniquely designed barges and ships; bromine was transported in specially designed returnable containers and in unique trucks; one-half ton and one ton bags were in use. Machine power replaced the muscle power that was prevalent at the beginning of the century.

Over the span of the 20th century, the demand for metals and minerals in the United States grew from a little over 160 million tons to about 3.3 billion tons; the ratio of renewable to nonrenewable materials used declined from 40:60 to about 10:90 during the century. Nonfuel minerals accounted for nearly the entire nonrenewable materials demand in 1900, and nonrenewable organic materials accounted for only about 2 million tons. In 2000, consumption of nonrenewable organic materials was equal to the approximately 135 million metric tons of all metals consumed during that year in the United States. However, a significant percentage of nonrenewable organics was attributed to inorganic fillers, extenders, and pigments, which are industrial minerals.

Sectors of the Economy

Agriculture

The 20th century brought developments in the tools used in agricultural processes and in the seed and feed used in the various sectors of agriculture. New machinery, including the gasoline tractor, the grain combine harvester, and the mechanical cotton picker, shifted the emphasis from manpower and horsepower to the faster, more efficient machinery. The development and widespread use of pesticides and fertilizer produced more and better crops, while the creation and increasing use of engineered crops produced better livestock and enhanced agricultural production.

Between 1900 and the end of World War I, the demand for

Digitized by Google

farm commodities was increasing. The postwar depression, however, severely affected farmers, until technology advancements that started in the 1930s aided in increasing the amount of land used for agricultural purposes. Although the Federal Government tried to help farmers with credit and cooperative management assistance, it was not until the creation of price supports, export subsidies, and soil conservation efforts in 1933 that agriculture received the help it needed. With the implementation of new technologies, the amount of land covered by farms in 1930 reached about 400 million hectares and remained at that level through 1980, and production during the same time period increased dramatically.

Communications

Of the discoveries of the 20th century, the radio, the television, and the telephone have been among the most important. Commercial radio broadcasting was established in 1920, and commercial television broadcasting, after World War II. By 1933, about two-thirds of American households had at least one radio, and about one-third had a telephone. By 1988, 97% of American households had at least one television set. Communications devices have had a profound impact on the culture, economy, lifestyle, and politics of the country. People have been able to watch events as they unfold, keep track of economic trends, and communicate with people half a world away. Media, politics, and entertainment have all benefitted from the advancements in the field of communications, as have emergency services, the economy, and many aspects of cultural life. The gap that time differences and distances had once created were being bridged by the end of the 20th century, bringing people, countries, and businesses closer together.

The metals and minerals industries have found a growing market in the various industries involved in communications, which purchase materials ranging from the metals required for cables and devices to nickel and lithium for batteries to germanium and silicon for semiconductors.

Construction

The 20th century saw the emergence of tall buildings, hydroelectric dams, high bridges, and highways that span the length and breadth of the country. Buildings of great height could be constructed because of steel-frame building techniques and the electric elevator. Skyscrapers, such as the World Trade Center and the Empire State Building in New York City and the Sears Tower in Chicago, which consumed large quantities of cement, ceramic tiles and sanitary ware, copper, glass, and steel, were almost exclusively a feature of the cities of North America for a good part of the 20th century. Late in the century, building of skyscrapers boomed in Asia.

Water power and associated dams, canals, and locks have been used for centuries; dams were used for flood control by maintaining water levels at navigable depths, to store water for drinking and irrigation, and to provide power. The widespread expansion of electric power grids and the constant increase in demand for electricity in the United States and worldwide prompted the construction of dams of unprecedented size during the 20th century.

Suspension bridges are impressive structures that transverse almost unbelievable distances. Although the first suspension bridges were built in the late 1800s, the highest and longest suspension bridges were built in the 20th century.

Another development of the 20th century was the increase in home ownership. Whereas in 1900, less than one-half of the U.S. population owned their own house, about two-thirds owned their house in 1990. Construction techniques and materials have changed drastically in the past 100 years to adapt to consumer, regulatory, and safety requirements and changing lifestyles, as well as those based on new technologies and materials.

Mining and Metal Processing

The technologic advancements that have been incorporated into consumer applications to make everyday living easier also have assisted industry to become more efficient, to produce more with fewer resources.

The mining and metal processing industries were among the first to take advantage of electricity, which was used to power trams and trains, underground and in-pit crushers, and conveyor systems that, combined with employing diesel- and diesel/electric-haulage vehicles, replaced the draft animals. By the end of the 20th century, the mining industry used machines of great size and power that operated at astounding rates and could mine continuously in underground mines and in surface operations. Additionally, innovative materials, such as synthetic greases and lubricants and metal alloys, were employed in critical wear areas to enhance their reliability. The various technologic advancements in mining and related technologies that took place during the century increased the quantity of material produced per employee.

Also during the 20th century, legislation to protect the health and safety of employees and regulations to protect the environment and the mining industry were promulgated. Mining and metal processing waste was regulated in an effort to protect the environment, and laws were enacted that would help miners who were injured on the job or who got sick because of their working conditions.

Innovation was not restricted to mining machinery and mining practices but also to ore processing and mineral separation. Mineral processing can have one or more of several goals depending on the nature of the ore and the desired end product. Early in the century, simple crushing, screening, and washing operations were augmented by such improvements as log washing, jigging, heavy media separation, and tabling that separated mineral species based on density. Later, froth flotation of finely crushed materials produced concentrates from low-grade ore; in-situ solution mining, solvent extraction, and heap leaching proved to be cost-effective ways of producing uranium, copper, and gold, respectively; and the unique Frasch method of underground melting of sulfur was practiced for most of the century. By combining processes, mining companies were able to produce multiple products from a single ore, which meant that they could mine ore bodies that would have been avoided early in the century owing to their leanness and could thus make a profit from the leaner ores.

Digitized by Google

Consumer Goods

There has been much technologic advancement since the early 19th century. Few fields have benefited more than the one that consists of applications used by consumers everyday. Such appliances as stoves, microwave ovens, refrigerators, and washing machines have made completing everyday tasks easier, and such applications of technology as televisions, telephones, computers, and compact disk (CD) players have provided a greater degree of comfort and entertainment than has been possible for more people than ever before. Some of these same devices have also facilitated the creation and operation of small businesses and self-employment, increasing the Nation's standard of living and helping the country's economy grow.

Health Services

The field of medicine and drugs has changed significantly over the past century. Where only a few drugs were used extensively and medical science was still in its early stages of evolution before 1900, the rate of advances grew drastically during the century and especially after World War II with such advances as genetic mapping, immunosuppressive drugs, magnetic resonance and x-ray imaging, and medical transplantation. One of the contributions of genetic mapping is the production of genetically engineered bacteria designed to break down oil slicks and industrial waste products.

Military

The 20th century was a time of great invention of military and defense applications. The airplane was used in World War I as a military machine for the first time and was enhanced during most of the century. The jet engine made the airplane one of the most widely used forms of commercial transportation, and developments such as breaking the sound barriers and the ability to take off and land vertically have made the airplane valuable to the defense of the Nation.

Other applications that were created by or for the military have found widespread use in consumer applications. One of the biggest developments of the late 20th century, the Internet, was initially developed as a network for the Department of Defense. The laser, which is used in such applications as CD and digital video disk (DVD) players, was created for military applications.

Transportation

At the beginning of the 20th century, the U.S. railroad system connected every major city, town, and hamlet in the Nation. Thousands of trains daily came and went from major cities. Electric streetcars serviced cities, and subways were set up in such cities as Boston and New York. Horses, carriages, mules, and wagons traversed cobble stone streets in the cities and dirt and gravel roads in rural areas. Steam-powered ferries plied the Nation's rivers, bays, inlets, and sounds. The railroads were major consumers of iron and steel for locomotives, rails, and bridges and of aggregates for roadbeds. Trolleys and subways were also consumers of iron and steel, and used copper for motors, switches, and lighting.

The adaptation of the combustion-ignition engine to the carriage led to a significant change in America by the 1920s. From a few "horseless carriages" in 1900 to millions of motorcars in the 1920s, the effects were astounding. Gone were the millions of draft animals, the stables and feed stores, and the mountains of dung. The almost universal adoption of the motorcar resulted in a cry for better roads and bridges, which had a positive effect on the construction industry, which was a major consumer of copper, cement, glass, sand and gravel, steel, and stone. The automobile industry became a major consumer of copper, glass, iron and steel, lead, and zinc. The effect of the automobile was not restricted to draft animals; ferries and railroads keenly felt it. Bridges of unprecedented size replaced ferries at many crossings; passenger rail service became unprofitable by 1930. Diesel-electric traction engines began replacing steam locomotives in the 1930s, and the transition was essentially complete by the early 1950s. By 1940, the Nation had over 3 million miles (about 5 million kilometers) of roads, of which only about one-half were paved.

After World War II, passenger air service greatly expanded, while buses and trucks proved more efficient than rail for service to smaller cities and to towns. Jet engine air passenger service, which was established in the late 1950s, had an additional adverse effect on long distance rail passenger service by shortening the time required for a journey.

The oil embargo of 1973 and adherence to government regulations on emissions and fleet gas mileage altered the automobile such that lighter weight metals and plastics were used to replace iron and steel where possible. Photochemical smog from engine exhaust was a problem in many areas. The automobile was partly responsible for urban sprawl late in the century. The population increase in the last half of the century, which led to urban sprawl and expansion of the suburbs, resulted in a great expansion of water and sewer, electric, telephone, and other public utilities systems, more and bigger roads, larger homes, more schools, more shopping centers, increased emergency services and law enforcement, more hospitals, and larger airports. The expansion placed high demands on the products of the minerals industry.

In 1900, one could cross the continent by rail in about a week; by 2000, one could go the same distance by air in under 8 hours. An ocean voyage to Europe was also about a week's journey; it was only a 10-hour trip by air in 2000. Much rail and most ocean vessel passenger service had been replaced by air service by the end of the 20th century. The movement of goods, however, remained the domain of trains, barges, and ocean vessels. Intermodal containers that could be transferred from rail to ship to truck without unloading were developed to enhance efficiency.

Environmental Considerations

Over the course of the century, the attitude that the Earth was nothing more than resources to be used changed slowly, and by the 1960s, the concept of mankind being stewards of the Earth started becoming more prevalent. In response to growing public demand for a cleaner environment, the government established standards to protect public health and to limit damage to

Digitized by Google

animals, crops, vegetation, and buildings. Some of the early results were a sharp decline in atmospheric lead and sulfur dioxide (SO_2) emissions.

Control of SO_2 emissions, which help reduce acid rain, affected different parts of the nonfuel minerals industry in opposing directions; recovery of SO_2 at smelters as sulfuric acid was costly and resulted in a byproduct that was not always readily salable. Although recovery of SO_2 at powerplants is also costly, it increased demand for sorbents, primarily lime and limestone, and the building materials needed to construct flue gas desulfurization facilities. The sulfur content of liquid fuels also was regulated and reduced SO_2 emissions from automobiles, trucks, and airplanes.

Since the late 1960s, recycling also became important and contributed to resource conservation, which became another issue of great concern for activists. Recycling is especially important because it removes material from the waste stream so disposal is not needed and it supplies raw materials that can go into new products usually at substantial energy savings compared with products made from virgin materials.

Conclusion

Patterns of consumption per capita of metals and minerals for developed economies have been stable in the latter part of the 20th century, and while there were lower rates of consumption in many developing countries, a number of developing countries had growing consumption per capita. The growth of metals and minerals consumption in developing countries could have a great impact on world mineral consumption.

In the future, satisfying the relatively modest per capita material requirements of these developing countries could strain industrial and financial systems and—potentially—environmental quality. Fostering sustainable development to meet such needs could be key to world peace and stability and could represent one of the major challenges for the physical and social sciences communities and the developed world for the next century.

SURVEY METHODS FOR NONFUEL MINERALS

By Kenneth W. Mlynarski

The U.S. Geological Survey (USGS) collects worldwide data on virtually every commercially important nonfuel mineral commodity. These data form the base for tracking and assessing the health of the minerals sector of the U.S. economy.

The USGS data collection activity was instituted by the 47th Congress in the appropriations act of August 7, 1882 (22 Stat. 329), which placed the collection of mineral statistics on an annual basis. The most recent authority for the USGS survey activity is the National Materials and Minerals Policy, Research and Development Act of 1980 (Public Law 96-479, 96th Congress). This act strengthens protection for proprietary data provided to the U.S. Department of the Interior by persons or firms engaged in any phase of mineral or mineral-material production or consumption.

Data Collection Surveys

The USGS begins the collection of domestic nonfuel minerals and materials statistics by appraising the information requirements of Government and private organizations of the United States. Requirements that can be met by collecting data from minerals establishments are posed as questions on USGS surveys. Figure 1 shows a typical survey form.

Specific questions about mineral commodity activities, such as production, consumption, and shipments, are structured in the survey forms to provide meaningful aggregated data. Thus, the entire mineral economic cycle from production through consumption is covered by 140 monthly, quarterly, semiannual, and annual surveys.

After the survey form has been designed, a list of the appropriate establishments to be canvassed is developed. Many sources are used to determine which companies, mines, plants, and other operations should be included on the survey mailing list. State geologists, Federal organizations (e.g., Mine Safety and Health Administration), trade associations, industry representatives, and trade publications and directories are some of the sources that are used to develop and update survey listings. With few exceptions, a complete canvass of the list of establishments is used rather than a sample survey. The iron and steel scrap industry is one of the exceptions where a sample survey is conducted.

The Paperwork Reduction Act requires that any Government agency wanting to collect information from 10 or more individuals or establishments must first obtain approval from the Office of Management and Budget (OMB). The OMB approves the need to collect the data and protects industry from unwarranted Government paperwork.

Survey Processing

The USGS surveys approximately 18,000 establishments. Each year, the USGS mails about 40,000 forms for 140 different surveys. Each completed survey form returned to the USGS undergoes extensive analysis to ensure the highest possible accuracy of the mineral data. The statistical staff monitors all surveys to ensure that errors are not created by reporting in physical units different from the units requested on the form. Relations between related measures, such as produced crude ore and marketable crude ore, are analyzed for consistency. Engineering relations, such as recovery factors from ores and concentrates, also are used. The totals for each form are verified, and currently reported data are checked against prior reports to detect possible errors or omissions.

For the majority of the surveys, which are automated, the forms are reviewed to ensure that data are complete and correct before entering into the computer database. The computer is programmed to conduct a series of automated checks to verify mathematical consistency and to identify discrepancies between the data reported and logically acceptable responses.

The USGS is modernizing and automating the minerals information survey-processing and data-dissemination functions. Automated commodity data system functions include computerized preparation of statistical tables, the use of desktop publishing to integrate text and tables, and electronic dissemination through the Internet. Information on minerals and mineral-related publications also is available through an easy-to-use automated fax response system known as MINES FaxBack.

Survey Responses.—To enable the reader to understand better the basis on which the statistics are calculated, each commodity annual report includes a section about domestic data coverage. This section briefly describes the data sources, the number of establishments surveyed, the response percentage, and the method of estimating the production or consumption for nonrespondents.

To produce reliable aggregated data, the USGS uses efficient procedures for handling instances of nonresponse. Failure to return the initial survey form results in a second mailing of the form. If the second form is not returned, then telephone calls are made to the nonrespondents. The followup calls provide the necessary data to complete the survey forms and/or to verify questionable data entries. Periodic visits to minerals establishments also are made by USGS mineral commodity specialists to gather missing data and to explain the importance of the establishment's reporting. By describing the use of the published statistics and showing the impact of nonresponse, the USGS strives to encourage respondents to give complete and accurate replies.

The OMB publication "Guidelines for Reducing Reporting Burden" stipulates that the minimum acceptable response rate is 75% of the panel surveyed. In addition, the USGS strives for a minimum reporting level of 75% of the quantity produced or consumed (depending on the survey) for certain key statistics.

Digitized by Google

Response rates are periodically reviewed. For those surveys not meeting the minimum reporting level, procedures are developed and implemented to improve response rates.

Estimation for Nonresponse.—When efforts to obtain a response to a survey fail, estimation or imputation techniques must be used to account for missing data. Some of the estimation methods depend on knowledge of prior establishment reporting, and other techniques rely on external information to estimate the missing data. When survey forms are received after the current publication has been completed, the forms are edited, necessary imputations are made for missing data, and the survey database is updated. The revised data are reported in later publications.

Protection of Proprietary Data.—The USGS relies on the cooperation of the U.S. minerals industry to provide the mineral data that are presented in this and other USGS publications. Without a strong response to survey requests, the USGS would not be able to present reliable statistics. The USGS, in turn, respects the proprietary nature of the data received from the individual companies and establishments. To ensure that proprietary rights will not be violated, the USGS analyzes each of the aggregated statistics to determine if the data reported by an individual establishment can be deduced from the aggregated statistics. If, for example, only two significant producers of a mineral commodity are in a given State, then the USGS will not publish the State total because either producer could readily estimate the production of the other. It is this obligation to protect proprietary information that results in the withheld, or W, entries in the published tables. If a company gives permission in writing, however, then the USGS will publish the data as long as the data from other respondents are protected from disclosure.

International Data

International data are collected by USGS country specialists and international data coordinators. The data are gathered from various sources, which include published reports of foreign Government mineral and statistical agencies, international organizations, the U.S. Department of State, the United Nations, the Organization of Petroleum Exporting Countries, and personal contact by specialists traveling abroad. Each February, annual minerals questionnaires that are sent to foreign organizations request them to provide estimates of mineral production for the host country for the preceding year. Missing data are estimated by USGS country specialists on the basis of historical trends and the specialist's knowledge of current production capabilities in each country.

Publications

The USGS disseminates current and historical minerals information through a broad range of printed publications.

The Minerals Yearbook summarizes annually, on a calendar-year basis, the significant economic and technical developments in the mineral industries. Three volumes are issued each year—volume I, Metals and Minerals; volume II, Area Reports—Domestic; and volume III, Area Reports—International. Volume I presents, by mineral commodity, salient statistics on production, trade, consumption, reserves, and other measures of economic activity. The chapters are issued separately as annual Mineral Industry Surveys (MIS) before the bound volume is available. Volume II reviews the U.S. minerals industry by State and island possessions. Volume III is published as four separate regional reports that cover more than 190 foreign countries. These reports contain individual country chapters that examine the mining, refining, processing, and use of minerals in each country in the region and how they relate to U.S. industry.

The MIS contain timely statistical and economic data on minerals. The surveys are designed to keep Government agencies and the public, particularly the mineral industry and the business community, informed of trends in the production, distribution, inventories, and consumption of minerals. Frequency of issue depends on the demand for current data. The MIS are released monthly, quarterly, semiannually, and annually.

Mineral Commodity Summaries (MCS), which is an up-to-date summary of about 80 nonfuel mineral commodities, is the earliest Government publication to furnish estimates that cover the previous year's nonfuel mineral industry data. It contains information on the domestic industry structure, Government programs, tariffs, 5-year salient domestic statistics, and a summary of significant events, trends, and issues in the international minerals industry during the past year.

Metal Industry Indicators (MII), which is published monthly, contains indexes that measure the current and future performance of five U.S. metal industries. For each of the five industries, a composite coincident index and a composite leading index have been developed based on procedures and data similar to those used to construct the Conference Board's coincident and leading cyclical indicators for the national economy. Leading and coincident indexes for the stone, clay, glass, and concrete products industry, which measure the current and future performance of the industrial minerals industry, also are published monthly. The indexes were designed by using the same procedures as the USGS metal composite indexes.

The MIS and the MII are available at no charge from Publication Distribution, Cochrans Mill Road, P.O. Box 18070, Pittsburgh, PA 15236, (412) 386-6156 or (412) 386-6160. Orders may be placed via electronic mail to pitpdrequests@cdc.gov. The Minerals Yearbooks and the MCS, may be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402, (202) 512-1800.

Some minerals information publications are also available on a CD-ROM format. The Minerals and Materials Information CD-ROM, which contains the Minerals Yearbooks, the MCS, and other publications, is updated three times per year. It is available from the Government Printing Office at the address and telephone number listed above.

Electronic Data Dissemination

In addition to the USGS printed publications, current

IRON ORE (Usable ore)

INDIVIDUAL COMPANY DATA – PROPRIETARY

Unless authorization is granted in the section above the signature, the data furnished in this report will be treated in confidence by the Department of the Interior, except that they may be disclosed to Federal defense agencies, or to the Congress upon official request for appropriate purposes. Unless objection is made in writing to the USGS, the information furnished in this report may be disclosed to the respondent's State Geological Survey (or similar State agency) if the State has appropriate safeguards to prevent disclosing company proprietary data.

(Please correct if name or address has changed)

FACSIMILE NUMBER
1-800-543-0661

Public voluntary reporting burden for this collection of information is estimated to average 30 MINUTES per response. A Federal agency may not conduct or sponsor, and a person is not required to respond to a collection of information unless it displays a valid OMB control number. Comments regarding this collection of information should be directed to: U.S. Geological Survey, Statistics and information Systems Section, 988 National Center, Reston, VA 20192; and/or Desk Officer for the Department of the Interior, Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20503. **Please do not mail survey forms to these addresses.**

Collection of nonfuel minerals information is authorized by Public Law 96-479 and the Defense Production Act. This information is used to support executive policy decisions pertaining to emergency preparedness, national defense, and analyses for minerals legislation and industrial trends. The USGS relies on your voluntary and timely response to assure that its information is complete and accurate.

Please return this form in the enclosed envelope or fax it to the above toll-free number by the **15TH OF THE MONTH** following the reporting period. Complete a separate form for each mineral establishment that was active during the reporting period. A minerals establishment is defined as a single physical location where mineral operations are conducted; for example, a mine only, a mine and preparation plant, or a preparation plant only. If you do not have exact data, please enter your best estimates and mark with an /e. Use zero (0) when appropriate. Do not report decimals or fractions. Round to the nearest whole number. If you have nothing to report, please complete Section 1, sign, and return the form. Please use the space for "Remarks" to provide any specific information that will help us in the use or interpretation of the data. Any statement on the effect of changes in economic conditions upon the reporting establishment will be useful. Additional forms are available upon request.

If you have any questions concerning completion of this form, please contact the Mineral Commodities Data Unit, U.S. Geological Survey, 985 National Center, Reston, VA 20192, Telephone (703) 648-7960.

SECTION 1. Mine or group covered by this report.

Name _____ State _____ County _____

SECTION 2. Stocks, production, and shipments of usable ore for the report month.

Report only ore products as shipped to consumer, such as direct-shipping ore, concentrate, or agglomerates.
Report ores produced in the United States only; do not include imports.

Usable ore (1)	Code	Weight unit Mark (X) one (2) Long tons (4)	Weight unit Mark (X) one (2) Metric tons (6)	Physical inventory Adjustment only (3)	Beginning stocks (4)	Production (5)	Shipments (6)	Ending stocks (7)
Iron ore (containing less that 5% Mn, natural.....	201							

SECTION 3. Please indicate any mines opened or closed by your company during the month.

Remarks:

Name of person to be contacted regarding this report			Tel. area code	No.	Ext.
Address	No.	Street	City	State	ZIP Code

STATISTICAL SUMMARY

By Stephen D. Smith

This annual report summarizes data on crude nonfuel mineral production[1] for the United States, its island possessions, and the Commonwealth of Puerto Rico.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this annual report is what is termed "mine output." This term refers to minerals or ores in the form in which they are first extracted from the ground, but customarily may include the output from auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. For copper, gold, lead, silver, and zinc, the quantities shown are recorded on a mine basis (as the recoverable content of ore sold or treated). The values assigned to the quantities, however, are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal. Values shown are in current dollars, with no adjustments made to compensate for changes in the purchasing power of the dollar.

The annual total value of all nonfuel mineral production in the United States increased almost 1% to $39.4 billion in 2000, with metals increasing almost 4% to $10.2 billion and industrial minerals decreasing less than 1% to $29.2 billion compared with those of 1999. Nine of the mineral commodities produced in the United States in 2000 had an individual total production value that was greater than $1 billion. These commodities were, in descending order, stone (crushed), cement (portland), sand and gravel (construction), gold, copper, iron ore (usable), lime, salt, and zinc. They composed almost 79% of the U.S. total production value (table 1).

In 2000, 13 States produced nonfuel mineral commodities with individual total production values of greater than $1 billion. These States were, in descending order, California, Nevada, Arizona, Texas, Florida, Michigan, Georgia, Minnesota, Utah, Missouri, Pennsylvania, Alaska, and New York. They composed slightly over 59% of the U.S. total production value (table 3).

---

[1]The terms "nonfuel mineral production" and related "values" encompass variations in meaning, depending on the minerals or mineral products. Production may be measured by mine shipments, mineral commodity sales, or marketable production (including consumption by producers) as is applicable to the individual mineral commodity.

All 2000 USGS mineral production data published in this chapter are as of January 2002. For some commodities such as construction sand and gravel, crushed stone, and portland cement, data are updated periodically. To obtain the most current information, please contact the appropriate USGS mineral commodity specialist. A telephone listing for the specialists may be retrieved over the Internet at URL http://minerals.usgs.gov/minerals/contacts/ comdir.html or by calling USGS information at (703) 648-4000 for the specialist's name and number. All Mineral Industry Surveys–mineral commodity, State, and country–also may be retrieved over the Internet at URL http://minerals.usgs.gov/minerals.

Values, percentage calculations, and rankings for 2000 may vary from the Minerals Yearbook, Area Reports: Domestic 2000, Volume II, owing to revision of preliminary 2000 to final 2000 data.

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 2000 1/

State	Value (thousands)	Rank	Percentage of total	Principal minerals, in order of value
Iowa	$503,000	28	1.28	Cement (portland), stone (crushed), sand and gravel (construction), gypsum (crude), lime.
Kansas	629,000	23	1.60	Cement (portland), helium (grade-A), salt, stone (crushed), helium (crude).
Kentucky	501,000	29	1.27	Stone (crushed), lime, cement (portland), sand and gravel (construction), clays (ball).
Louisiana	325,000	35	0.83	Salt, sulfur (Frasch), sand and gravel (construction), stone (crushed), sand and gravel (industrial).
Maine	95,500	43	0.24	Sand and gravel (construction), cement (portland), stone (crushed), cement (masonry), peat.
Maryland 2/	358,000	34	0.91	Stone (crushed), cement (portland), sand and gravel (construction), cement (masonry), stone (dimension).
Massachusetts 2/	200,000	39	0.51	Stone (crushed), sand and gravel (construction), stone (dimension), lime, clays (common).
Michigan	1,640,000	6	4.17	Cement (portland), iron ore (usable), sand and gravel (construction), stone (crushed), magnesium compounds.
Minnesota	1,460,000	8	3.70	Iron ore (usable), sand and gravel (construction), stone (crushed), stone (dimension), sand and gravel (industrial).
Mississippi	149,000	41	0.38	Sand and gravel (construction), clays (fuller's earth), cement (portland), stone (crushed), sand and gravel (industrial).
Missouri	1,370,000	10	3.48	Stone (crushed), cement (portland), lead, lime, zinc.
Montana	596,000	25	1.51	Palladium, gold, platinum, cement (portland), sand and gravel (construction).
Nebraska 2/	83,700	45	0.21	Cement (portland), stone (crushed), sand and gravel (construction), lime, cement (masonry).
Nevada	2,980,000	2	7.56	Gold, sand and gravel (construction), silver, lime, cement (portland).
New Hampshire 2/	57,100	47	0.14	Sand and gravel (construction), stone (crushed), stone (dimension), gemstones.
New Jersey 2/	291,000	37	0.74	Stone (crushed), sand and gravel (construction), sand and gravel (industrial), greensand marl, peat.
New Mexico	786,000	18	2.00	Copper, potash, sand and gravel (construction), cement (portland), stone (crushed).
New York	1,020,000	13	2.58	Stone (crushed), salt, cement (portland), sand and gravel (construction), zinc.
North Carolina	744,000	19	1.89	Stone (crushed), phosphate rock, sand and gravel (construction), sand and gravel (industrial), feldspar.
North Dakota	35,200	48	0.09	Sand and gravel (construction), lime, stone (crushed), clays (common), sand and gravel (industrial).
Ohio	999,000	14	2.54	Stone (crushed), sand and gravel (construction), salt, lime, cement (portland).
Oklahoma	473,000	31	1.20	Stone (crushed), cement (portland), sand and gravel (construction), sand and gravel (industrial), gypsum (crude).
Oregon	299,000	36	0.76	Stone (crushed), sand and gravel (construction), cement (portland), diatomite, lime.
Pennsylvania 2/	1,250,000	11	3.17	Stone (crushed), cement (portland), sand and gravel (construction), lime, cement (masonry).
Rhode Island 2/	20,300	49	0.05	Stone (crushed), sand and gravel (construction), sand and gravel (industrial), gemstones.
South Carolina	551,000	27	1.40	Cement (portland), stone (crushed), cement (masonry), sand and gravel (construction), clays (kaolin).
South Dakota	233,000	38	0.59	Gold, cement (portland), sand and gravel (construction), stone (crushed), stone (dimension).
Tennessee	737,000	20	1.87	Stone (crushed), zinc, cement (portland), sand and gravel (construction), clays (ball).
Texas	1,950,000	4	4.95	Cement (portland), stone (crushed), sand and gravel (construction), lime, salt.
Utah	1,430,000	9	3.64	Copper, gold, cement (portland), sand and gravel (construction), salt.
Vermont 2/	66,900	46	0.17	Stone (dimension), stone (crushed), sand and gravel (construction), talc (crude), gemstones.
Virginia	710,000	21	1.80	Stone (crushed), cement (portland), sand and gravel (construction), lime, clays (fuller's earth).
Washington	607,000	24	1.54	Sand and gravel (construction), stone (crushed), magnesium metal, cement (portland), gold.
West Virginia	172,000	40	0.44	Stone (crushed), cement (portland), sand and gravel (industrial), lime, salt.
Wisconsin 2/	372,000	32	0.94	Sand and gravel (construction), stone (crushed), lime, sand and gravel (industrial), stone (dimension).
Wyoming	978,000	15	2.48	Soda ash, clays (bentonite), helium (grade-A), cement (portland), stone (crushed).
Undistributed	157,000	XX	0.40	
Total	39,400,000	XX	100.00	

XX Not applicable.
1/ Data are rounded to three significant digits; may not add to totals shown.
2/ Partial total; excludes values that must be concealed to avoid disclosing company proprietary data. Concealed values included with "Undistributed."

TABLE 6
NONFUEL RAW MINERAL PRODUCTION IN THE COMMONWEALTH OF PUERTO RICO AND ISLANDS ADMINISTERED BY THE UNITED STATES 1/ 2/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral		1998 Quantity	1998 Value	1999 Quantity	1999 Value	2000 Quantity	2000 Value
Puerto Rico:							
Cement, portland	metric tons	1,590	W	W	W	1,660	W
Clays, common		W	W	159	W	141	458
Lime		37	4,800	27	3,770	16	2,750
Salt		45	1,500	45	1,500	45	1,500
Stone, crushed		12,700	58,600	13,200	56,800	10,800	51,000
Combined values of sand and gravel (industrial), and stone (dimension marble), and values indicated by symbol W		XX	156,000	XX	178,000	XX	193,000
Total		XX	221,000	XX	240,000	XX	249,000
Administered Islands:							
American Samoa, stone, crushed		W	(3/)	W	(3/)	--	--
Guam, stone, crushed		1,850	14,100	1,740	11,800	121	856
Virgin Islands, stone, crushed limestone and traprock		W	(3/)	W	(3/)	W	(3/)
Total		XX	14,100	XX	11,800	XX	856

W Withheld to avoid disclosing company proprietary data; value included with "Combined values" data. XX Not applicable. -- Zero.
1/ Production as measured by mine shipments, sales, or marketable production (including consumption by producers).
2/ Data are rounded to three significant digits; may not add to totals shown.
3/ Withheld to avoid disclosing company proprietary data.

TABLE 7
U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals:					
Aluminum:					
Crude and semicrude	metric tons	1,640,000	3,530,000	1,760,000	3,880,000
Manufactures	do.	106,000	374,000	100,000	388,000
Antimony:					
Metal, alloys, waste and scrap	do.	473	1,810	1,080	2,820
Oxide, antimony content	do.	3,190	10,000	6,040	14,200
Arsenic metal	do.	1,350	4,650	41	5,620
Bauxite and alumina:					
Alumina, calcined equivalent		1,230	435,000	1,090	452,000
Bauxite:					
Calcined, refractory and other grade		34	6,570	9	1,800
Crude and dried		115	10,100	133	8,950
Speciality aluminum compounds, sulfate, chloride, fluoride-based	metric tons	38,800	29,300	32,800	29,200
Beryllium, alloys, wrought or unwrought, and waste and scrap	kilograms	39,600	6,770	33,900	5,410
Bismuth, metal, alloys, and waste and scrap, bismuth content	do.	257,000	2,000	491,000	4,840
Cadmium:					
Metal, includes alloys and scrap	do.	20,400	523	312,000	1,140
Sulfide, gross weight	do.	107,000	28	1,110,000	607
Chromium:					
Chemicals	metric tons	41,800	55,600	37,200	60,400
Chromite ore and concentrate	do.	110,000	8,580	138,000	10,200
Metals, alloys, ferroalloys	do.	8,160	22,100	39,000	34,300
Pigments and preparations	do.	1,470	6,200	1,040	5,340
Cobalt:					
Metal:					
Unwrought, powders, waste and scrap, mattes, other intermediate products of metallurgy	do.	1,100	34,000	1,520	54,500
Wrought and cobalt articles	do.	546	26,400	971	37,800
Oxides and hydroxides	do.	521	8,140	1,320	11,700
Other forms, acetates and chlorides	do.	307	3,100	676	3,650

See footnotes at end of table.

TABLE 7--Continued
U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Columbium (niobium) and tantalum:					
Columbium:					
Ferrocolumbium	metric tons	166	1,110	60	526
Ores and concentrates	do.	12	566	55	830
Tantalum:					
Ores and concentrates, includes synthetic	do.	317	7,280	354	11,600
Unwrought, alloys, metal, powders, waste and scrap	do.	418	65,000	429	99,200
Wrought	do.	132	43,500	139	47,500
Copper:					
Scrap, alloyed and unalloyed	do.	315,000	366,000	486,000	536,000
Semimanufactures	do.	150,000 r/	473,000 r/	188,000	638,000
Unmanufactured, does not include unalloyed scrap, copper content	do.	146,000 r/	204,000 r/	255,000	398,000
Ferroalloys not listed elsewhere:					
Ferrophosphorous	do.	1,100	699	4,510	3,110
Ferrotitanium and ferrosilicon-titanium	do.	1,210	2,650	1,090	2,990
Ferrozirconium	do.	51	155	213	482
Ferroalloys, other	do.	3,370	6,030	3,020	6,380
Gold:					
Bullion, refined	kilograms	435,000	3,880,000	440,000	4,030,000
Compounds	do.	561,000	14,100	1,390,000	15,300
Doré and precipitates	do.	87,300	778,000	106,000	924,000
Metal powder	do.	270	2,800	1,130	10,700
Ores and concentrates	do.	117	1,180	745	9,680
Waste and scrap	do.	40,000	302,000	64,100	700,000
Indium e/	metric tons	25	5,500	15	3,300
Iron and steel:					
Cast iron and steel products		203	447,000	202	445,000 e/
Fabricated steel products		1,120	3,640,000	1,050	3,410,000 e/
Steel mill products		4,920	4,260,000	5,920	5,120,000 e/
Iron and steel scrap:					
Direct-reduced iron, steelmaking grade		3	302	2	241
Ferrous, includes tinplate and terplate, excludes used rails for rerolling and other uses, ships, boats, other vessels for scrapping		5,520	738,000	5,760	1,000,000
Pig iron, all grades		83	11,100	72	9,620
Ships, boats, other vessels for scrapping		7	2,610	11	153
Used rails for rerolling and other uses, includes mixed (new plus used) rails		34 r/	14,300	40	15,600
Iron ore		6,120	243,000	6,150	246,000
Lead, lead content:					
Ash and residues	metric tons	1,430	2,000	11,300	18,400
Base bullion	do.	64,100	76,200	32,100	75,300
Ore and concentrate	do.	93,500	33,400	117,000	42,600
Scrap, gross weight	do.	117,000	22,000	71,600	13,200
Unwrought and alloys	do.	23,400	17,700	21,400	23,800
Wrought and alloys	do.	13,900	38,500	27,200	57,600
Magnesium:					
Alloys, gross weight	do.	2,760	11,300	6,020	23,300
Metal	do.	4,790	14,600	7,300	20,200
Powder, sheets, tubing, ribbons, wire, other forms, gross weight	do.	4,990	20,200	4,060	24,000
Waste and scrap	do.	16,500	46,500	6,400	17,500
Manganese:					
Ferromanganese, all grades	do.	11,600	6,510	7,950	5,290
Metal, including alloys, waste and scrap	do.	3,540	7,940	2,220	5,020
Ore and concentrates with 20% or more manganese	do.	4,170	651	10,000	2,200
Silicomanganese	do.	3,700	2,180	1,870	1,200
Mercury	do.	181	1,120	178	2,040
Molybdenum, molybdenum content:					
Ferromolybdenum	do.	1,510	12,400	1,230	9,940
Ore and concentrates, including roasted and other	do.	27,900	129,000	23,600	104,000
Oxides and hydroxides, gross weight	do.	1,130	8,510	1,190	8,560
Molybdates, all	do.	1,300	7,050	1,080	7,530
Powder, gross weight	do.	362	7,540	300	6,940

See footnotes at end of table.

TABLE 7--Continued
U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Molybdenum, molybdenum content--Continued:					
Unwrought, gross weight	metric tons	167	2,430	228	3,550
Wire, gross weight	do.	200	13,900	150	9,300
Wrought, gross weight	do.	147	8,050	185	9,610
Nickel, nickel content:					
Alloyed, gross weight	do.	27,300	371,000	28,700	433,000
Unwrought:					
Primary and chemicals, includes carbonate	do.	7,440	140,000	8,150	124,000
Secondary	do.	31,400	192,000	49,900	371,000
Wrought	do.	922	11,500	1,410	23,700
Platinum-group metals, metal content:					
Iridium, osmium, ruthenium	kilograms	851	11,200	1,480	17,200
Palladium	do.	43,800 r/	271,000 r/	58,600	518,000
Platinum	do.	27,100	520,000	32,400	505,000
Rhodium	do.	114	5,310	797	50,800
Rare-earths, estimated REO content:					
Cerium compounds	do.	3,960,000	18,400	4,050,000	19,000
Compounds	do.	1,690,000	19,600	1,760,000	24,700
Ferrocerium and other pyrophoric alloys	do.	2,360,000	10,700	2,300,000	7,620
Metals, including scandium and yttrium	do.	1,600,000	5,280	1,650,000	9,830
Selenium, metal, waste and scrap, selenium content	do.	233,000	1,900	82,100	583
Silicon, gross weight:					
Ferrosilicon	metric tons	46,600	40,100	43,300	41,900
Metal	do.	37,700	281,000	18,900	334,000
Silver, silver content:					
Bullion	kilograms	481,000	84,400	279,000	46,100
Doré	do.	64,400	11,400	36,000	6,440
Metal powder, gross weight	do.	324,000	55,100	424,000	89,700
Nitrate, gross weight	do.	62,500	7,330	217,000	29,400
Ores and concentrates	do.	70,800	14,200	65,100	9,110
Semimanufactured forms containing 99.5% or more by weight of silver, gross weight	do.	122,000	28,700	148,000	35,200
Waste and scrap, gross weight	do.	1,310,000	223,000	1,670,000	377,000
Unwrought, other, gross weight	do.	75,100	14,400	57,500	11,500
Thorium and thorium-bearing materials, compounds	do.	2,520	318	4,640	478
Tin:					
Ingots and pigs	metric tons	6,770	38,100	6,640	35,300
Tin scrap and other tin bearing material, except tinplate scrap, includes rods, profiles, wire, powders, flakes, tubes, pipes	do.	33,200	56,100 r/	26,200	48,800
Tinplate and terneplate	do.	290,000	172,000	300,000	163,000
Titanium:					
Metal:					
Wrought, bars, rods, other	do.	5,260	239,000	5,380	253,000
Unwrought:					
Sponge and waste and scrap	do.	8,940	17,500	6,990	24,100
Other, billet, blooms, sheet bars, ingot	do.	2,470	58,400 r/	3,200	82,500
Ores and concentrates	do.	9,380	5,350	18,900	7,920
Pigments, dioxide and oxides	do.	384,000	627,000	464,000	784,000
Tungsten, tungsten content:					
Ammonium paratungstate	do.	103	911	53	489
Carbide powder	do.	701	16,900	969	19,000
Metal powders	do.	711	19,000	467	17,000
Miscellaneous tungsten-bearing materials, ferrotungsten, ferrosilicon tungsten, unwrought, waste and scrap, wrought, other metal, compounds	do.	1,340	33,900	1,310	35,400
Ores and concentrates	do.	26	826	70	2,050
Vanadium:					
Aluminum-vanadium master alloy, gross weight	kilograms	514,000	6,440	667,000	9,120
Ferrovanadium, vanadium content	do.	213,000	3,180	172,000	2,360
Metal, including waste and scrap, gross weight	do.	177,000	3,200	105,000	1,680
Pentoxide, anhydride, vanadium content	do.	747,000	4,270	653,000	3,360
Other oxides and hydroxides, vanadium content	do.	69,700	656	99,800	741

U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Zinc:					
Compounds, chloride, compounds, n.s.p.f., oxide, sulfate	metric tons	16,100	20,100	22,600	55,200
Ores and concentrates, zinc content	do.	531,000	317,000	523,000	298,000
Slab	do.	1,880	2,220	2,770	3,380
Rolled	do.	3,870	5,500	3,530	5,350
Zirconium:					
Ore and concentrates	do.	69,500	27,300	72,900	34,000
Oxide, includes germanium oxides and zirconium oxides	do.	1,680	14,100	2,220	18,600 e/
Unwrought and waste and scrap	do.	156	3,160	180	3,620
Total		XX	24,600,000 r/	XX	28,200,000
Industrial minerals:					
Abrasives, manufactured:					
Aluminum oxide, crude	metric tons	9,020	20,400	9,020	23,500
Boron carbide	do.	17	652	29	481
Metallic abrasives	do.	26,600	17,900	28,900	18,600
Silicon carbide, crude, ground and refined	do.	8,560 r/	10,900 r/	10,000	11,500
Asbestos, includes reexports:					
Manufactured		NA	237,000	NA	288,000
Unmanufactured	metric tons	21,700	7,960	18,800	7,220
Barite, natural barium sulfate	do.	21,800	2,750	36,300	4,180
Boron minerals and compounds:					
Boric acid, includes orthoboric and anhydrous		107	56,700	119	64,400
Sodium borates		370	180,000	413	136,000
Bromine:					
Compounds, includes methyl bromine and ethylene dibromide, contained bromine	metric tons	8,020	16,000	7,740	26,200
Elemental	do.	2,110	2,430	1,870	2,560
Cement, hydraulic and clinker		694	55,200	738	64,200
Clays:					
Ball		107	6,080	100	8,660
Bentonite		719	75,300	761	80,300
Fire		189	16,500	216	18,600
Fuller's earth		152	24,600	136	25,000
Kaolin		3,310	567,000	3,690	621,000
Other, n.e.c., includes chamotte or dinas earth, activated clays and earths, artifically activated clays		329	133,000	357	142,000
Diamond, includes reexports, excludes industrial diamond	thousand carats	5,440	3,080,000	16,300	3,980,000
Diamond, industrial (exports and reexports):					
Powder, dust and grit, natural and synthetic	do.	101,000	68,100	100,000	71,800
Stones, unworked	do.	3,970	36,700	3,620	34,600
Diatomite		123	39,700	131	40,800
Feldspar	metric tons	9,880 r/	1,160	11,400	1,490
Fluorspar	do.	55,400	6,970	39,800	5,330
Garnet, industrial e/		10	5,000	10	5,000
Graphite, natural and artificial 2/	metric tons	102,000	82,800	94,100	96,500
Gypsum and gypsum products:					
Boards		52	22,900	58	27,100
Crude		112	11,000	161	12,600
Plasters		588	32,000	248	30,200
Other		XX	27,400	XX	32,200
Helium, grade-A	million cubic meters	27	47,400	37	66,000
Iodine, crude/resublimed and potassium iodide	metric tons	1,130	18,000	1,130	15,000
Iron oxide pigments and hydroxides:					
Pigment grade	do.	13,800	15,200	9,640	17,200
Other grade	do.	30,100	59,800	30,900	46,500
Lime		59	8,270 r/	73	9,960
Lithium chemicals:					
Carbonate	metric tons	2,710	9,670	2,770	9,630
Hydroxide	do.	4,940	21,200	4,780	31,100

See footnotes at end of table.

TABLE 7--Continued
U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Industrial minerals--Continued:					
Magnesium compounds:					
Compounds, chlorides, hydroxide and peroxide, sulfates	metric tons	28,900	12,300	31,800	29,600
Magnesite, crude and processed:					
Caustic-calcined magnesia	do.	3,190	1,680	11,600	8,470
Crude	do.	28,900	3,520	29,500	3,460
Dead-burned and fused magnesia	do.	66,700	25,200	59,800	22,400
Other magnesia	do.	15,800	13,300	21,400	19,000
Mica:					
Scrap and flake:					
Powder	do.	7,320	4,010	8,880	4,610
Waste	do.	3,950	1,290	1,380	383
Sheet:					
Unworked	do.	452	2,150	209	343
Worked	do.	840	16,600	1,070	17,100
Peat		40	4,310	37	3,490
Perlite, processed and expanded e/	metric tons	47,000	1,570	43,000	1,450
Phosphate rock		272	11,400	299	12,100
Pumice and pumicite		23	10,100	27	15,300
Salt		892	37,000	642	37,800
Sand and gravel:					
Construction:					
Gravel		378	7,080	270	3,030
Sand		1,270	20,800	2,140	21,200
Industrial		1,670	133,000	1,660	179,000
Silica:					
Quartz crystal, cultured, electronic- and optical-grade	metric tons	90	25,400	74	22,800
Special silica stone products		NA	6,400	NA	6,400
Soda ash		3,620	447,000	3,900	477,000
Stone:					
Crushed		4,120	30,800	4,020	29,700
Dimension		XX	54,500	XX	59,800
Strontium:					
Carbonate, precipitated	metric tons	3,860	2,470	6,320	4,250
Oxide, hydroxide, peroxide	do.	854	470	862	466
Sulfur:					
Elemental		685	35,800	762	53,700
Sulfuric acid, 100% H_2SO_4	metric tons	155,000	16,800	191,000	15,800
Talc, excludes powders, talcum in (package), face, compact		147	27,200	154	32,800
Vermiculite e/		13 r/	1,640 r/	5	590
Wollastonite e/		20,000	8,000	7,000	2,800
Zeolites e/	metric tons	500 r/	100	200	40
Total		XX	5,990,000 r/	XX	7,160,000
Grand total		XX	30,600,000 r/	XX	35,300,000

e/ Estimated. r/ Revised. NA Not available. XX Not applicable. -- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Artificial graphite includes large amounts of materials made from petroleum coke.

TABLE 8
U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals:					
Aluminum:					
Crude and semicrude	metric tons	4,000,000	6,200,000	3,910,000	6,860,000
Manufactures	do.	191,000	452,000	211,000	538,000
Antimony:					
Metal	do.	14,800	18,500	14,200	19,100

See footnotes at end of table.

TABLE 8--Continued
U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Antimony--Continued:					
Ore and concentrate, antimony content	metric tons	2,870	3,350	3,690	4,250
Oxide, antimony content	do.	19,100	28,900	23,700	36,500
Arsenic:					
Acid	do.	4	24	--	--
Metal	do.	1,300	8,390	830	9,800
Trioxide	do.	29,100	14,700	31,100	15,500
Bauxite and alumina:					
Alumina, calcined equivalent		3,810	845,000	3,820	933,000
Bauxite:					
Calcined, refractory and other grade		299	28,000	310	26,600
Crude and dried		9,890	281,000	8,550	193,000
Speciality aluminum compounds, sulfate, chloride, fluoride-based	metric tons	51,200	31,500	46,700	26,000
Beryllium, ore, metal, and compounds	kilograms	136,000	2,620	164,000	3,260
Bismuth, metallic	do.	2,110,000	15,300	2,410,000	19,100
Cadmium:					
Metal	do.	294,000	848	425,000	1,510
Sulfide, gross weight	do.	18,400	95	45,400	169
Chromium:					
Chemicals	metric tons	22,900	39,600	29,100	27,300
Chromite ore	do.	252,000	15,700	268,000	17,100
Ferrochromium, metals, alloys	do.	649,000	334,000	608,000	339,000
Pigments and preparations based on chromium	do.	9,590	30,000	10,200	32,100
Cobalt:					
Metal:					
Alloys, articles, matte, wrought, waste and scrap	do.	819	22,600	1,120	29,300
Unwrought, excluding alloys and waste and scrap	do.	6,800	229,000	7,210	213,000
Oxide and hydroxides	do.	1,260	33,700	1,540	37,100
Other forms, includes acetates, carbonates, chlorides, sulfates	do.	1,610	12,400	1,710	11,000
Columbium (niobium) and tantalum:					
Columbium:					
Ferrocolumbium	do.	6,850	62,200	6,770	62,100
Ores and concentrates	do.	95	1,620	151	1,680
Oxide	do.	1,720 r/	30,600	1,700	29,200
Unwrought, alloys, metals, powder	do.	468	13,500	606	16,900
Tantalum:					
Ores and concentrates	do.	992	33,600	2,080	74,800
Unwrought, alloys, metal, powders, waste and scrap	do.	997	68,400	1,060	104,000
Wrought	do.	56	13,600	43	14,900
Copper:					
Scrap, alloyed and unalloyed	do.	108,000	168,000 r/	112,000	186,000
Semimanufactures	do.	313,000 r/	672,000 r/	397,000	1,000,000
Unmanufactured, does not include unalloyed scrap, copper content	do.	1,170,000	1,910,000	1,250,000	2,400,000
Ferroalloys not listed elsewhere:					
Ferrophosphorus	do.	10,600	3,050	13,000	3,310
Ferrotitanium and ferrosilicon-titanium	do.	4,750	8,620	6,050	15,900
Ferrozirconium	do.	100	173	281	548
Ferroalloys, other	do.	32,000	46,600	31,400	42,400
Gallium, unwrought and waste and scrap	kilograms	24,100	10,400	39,400	18,400
Germanium materials, gross weight	do.	12,400	10,400	8,210	9,240
Gold:					
Ash and residues	do.	133	1,760	60	1,800
Bullion, refined	do.	196,000	1,790,000	184,000	1,680,000
Compounds	do.	9,400	59,700	7,970	60,500
Doré and precipitates	do.	24,700	210,000	39,000	292,000
Metal powder	do.	5,500	48,700	6,720	58,800
Ores and concentrates	do.	117	1,130	65	636
Waste and scrap	do.	30,500	94,100	29,800	71,200
Indium, unwrought and waste and scrap	do.	77,400	14,500	69,400	9,620
Iron and steel:					
Cast iron and steel products		505	410,000	557	453,000 e/

See footnotes at end of table.

TABLE 8--Continued
U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Iron and steel--Continued:					
Fabricated steel products		4,020	5,780,000	4,240	6,090,000 e/
Stainless steel	metric tons	696,000	1,680,000	757,000	1,830,000 e/
Steel mill products		32,400	12,600,000	34,400	13,400,000 e/
Iron and steel scrap:					
Direct-reduced iron, steelmaking grade		950	86,500	1,090	119,000
Ferrous, includes tinplate and ternplate, excludes used rails for rerolling and other uses, ships, boats, other vessels for scrapping		3,670	383,000	3,350	385,000
Pig iron, all grades		4,990	527,000	4,970	601,000
Ships, boats, other vessels for scrapping		(2/)	189	--	--
Used rails for rerolling and other uses, includes mixed (new plus used), rails		348	43,900	271	34,100
Iron ore		14,300	399,000	15,700	420,000
Lead, lead content:					
Base bullion	metric tons	90	58	65	30
Ore and concentrates	do.	12,300	3,100	31,200	7,810
Pigments and compounds, gross weight	do.	37,700	56,100	40,300	57,600
Pigs and bars	do.	311,000	175,000	356,000	190,000
Scrap, reclaimed, includes ash and residues	do.	--	--	25	5
Wrought, all forms, including wire and powders, gross weight	do.	11,800	18,300	9,200	19,300
Magnesium:					
Alloys, magnesium content	do.	56,500	180,000	56,300	164,000
Metal	do.	26,900	78,000	22,900	58,700
Powder, sheets, tubing, ribbons, wire, other forms, magnesium content	do.	594	2,260 r/	2,300	8,670
Waste and scrap	do.	6,780	7,690	9,890	16,400
Manganese, manganese content:					
Chemicals, manganese dioxide and potassium permanganate, gross weight	do.	42,600	61,200	52,700	75,700
Ferromanganese, all grades	do.	245,000	149,000	246,000	151,000
Metal, unwrought, waste and scrap, other, gross weight	do.	15,100	22,900	16,200	24,700
Ore and concentrates with 20% or manganese, all grades	do.	224,000	37,200 r/	227,000	32,100
Silicomanganese	do.	202,000	121,000	252,000	169,000
Mercury	do.	62	301	103	1,130
Molybdenum, molybdenum content:					
Ferromolybdenum	do.	5,160	37,300	5,310	35,600
Molybdates, all	do.	813	7,380	1,550	13,400
Ore and concentrates, roasted and other	do.	6,390	35,700	6,120	35,500
Oxides and hydroxides, gross weight	do.	746	5,100	1,210	7,400
Powders	do.	106	3,240	125	3,770
Unwrought	do.	13	542	16	328
Wire, gross weight	do.	8	638	17	894
Other, orange, mixtures of inorganic compounds, waste and scrap, other, gross weight	do.	2,030	14,500	2,100	14,600
Nickel, nickel content:					
Alloyed, gross weight	do.	13,300	184,000	19,000	270,000
Unwrought:					
Primary and chemicals, excludes carbonate	do.	139,000	854,000	156,000	1,410,000
Secondary	do.	9,480	54,800	10,700	91,900
Wrought	do.	1,090	17,900	992	20,400
Platinum-group metals, metal content:					
Iridium, unwrought and other forms	kilograms	2,250 r/	25,100	2,700	27,400
Osmium, unwrought	do.	23	272	133	1,130
Palladium, unwrought and other	do.	189,000	2,090,000	182,000	3,470,000
Platinum	do.	125,000 r/	1,150,000	94,000	1,360,000
Rhodium, unwrought and other forms	do.	10,300 r/	274,000 r/	18,200	851,000
Ruthenium, unwrought	do.	11,400	14,700	20,900	49,600
Rare-earths, estimated REO content:					
Cerium compounds, including oxides, hydroxides, nitrates, sulfate chlorides, oxalates	do.	3,990,000	26,200	4,310,000	29,400
Compounds, including oxides, hydroxides, nitrates, other compounds except chlorides	do.	7,760,000	71,600	11,200,000	71,300
Ferrocerium and other pyrophoric alloys	do.	120,000	1,920	118,000	1,560
Metals, whether intermixed or alloyed	do.	1,780,000 r/	18,500	2,470,000	23,700

See footnotes at end of table.

TABLE 8--Continued
U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Rare-earths, estimated REO content--Continued:					
Mixtures of rare-earth chlorides, except cerium chloride	kilograms	1,530,000	6,960	1,330,000	3,980
Mixtures of rare-earth oxides except cerium oxide	do.	5,980,000	15,500	2,190,000	9,530
Yttrium compounds content by weight greater than 19% but less than 85% oxide equivalent	do.	161,000	3,200	58,400	2,590
Rhenium:					
Ammonium perrhenate	do.	2,750	1,670	7,450	3,830
Metal	do.	12,800	14,000	10,700	10,800
Selenium and tellurium:					
Selenium, selenium content:					
Unwrought and waste and scrap	do.	311,000	3,110	452,000	2,670
Selenium dioxide	do.	15,700	160	24,300	186
Tellurium, unwrought, and waste and scrap, gross weight	do.	38,000	1,440	52,300	1,800
Silicon, gross weight:					
Ferrosilicon	metric tons	246,000	160,000	322,000	193,000
Metal	do.	116,000	235,000	133,000	249,000
Silver, silver content:					
Ash and residues	kilograms	101,000	8,970	55,800	7,340
Bullion	do.	2,660,000	453,000	3,810,000	629,000
Doré	do.	407,000 r/	81,600	73,900	17,600
Metal powder, gross weight	do.	120,000	26,400	235,000	46,500
Nitrate, gross weight	do.	4,480 r/	364	24,200	1,770
Ore and concentrates:					
Base metal	do.	2,750	440	--	--
Silver	do.	10,800	1,970	1,420	229
Semimanufactured forms containing 99.5% or more by weight of silver, gross weight	do.	137,000 r/	23,900 r/	140,000	25,800
Waste and scrap, gross weight	do.	1,640,000	123,000 r/	1,130,000	134,000
Unwrought, other, gross weight	do.	126,000	22,200	204,000	37,200
Thallium, unwrought, waste and scrap, powders	do.	838	139	100	24
Thorium and thorium-bearing materials, compounds	do.	5,290	280	11,100	528
Tin, gross weight:					
Compounds	metric tons	411	3,550	586	4,740
Dross, skimmings, scrap, residues, alloys, n.s.p.f.	do.	3,870	7,840	5,170	17,700
Metal, unwrought	do.	47,500	255,000	44,900	244,000
Miscellaneous, includes tinfoil, tin powder, flitters, metallics, manufactures, n.s.p.f.	do.	NA	4,830	NA	5,680
Tinplate and terneplate	do.	449,000	255,000	359,000	206,000
Tinplate scrap	do.	58,000	5,270	14,500	1,660
Titanium:					
Concentrates:					
Ilmenite	do.	391,000	32,800	386,000	37,200
Rutile, natural and synthetic	do.	344,000	140,000	438,000	169,000
Slag	do.	678,000	265,000	533,000	219,000
Titaniferous iron ore	do.	10,700	2,620	88,200	4,890
Pigments, dioxides and oxides	do.	225,000	406,000	218,000	389,000
Metal:					
Unwrought:					
Ingots and billets	do.	1,380	20,400	1,540	23,200
Other, includes blooms, sheet, bars, slabs, other unwrought	do.	10	423	23	398
Powder	do.	224	1,170	250	2,610
Sponge	do.	6,000	42,200	7,240	49,900
Waste and scrap	do.	6,870	19,500	7,550	24,100
Wrought products, bars, castings, foil, pipes, plates, profiles, rods, sheet, strip, tubes, wire, other	do.	2,910	74,100	2,900	60,600
Tungsten, tungsten content:					
Ammonium paratungstate	do.	1,920	10,200	2,270	13,400
Ferrotungsten and ferrosilicon tungsten	do.	669	3,760	470	2,600
Miscellaneous tungsten-bearing materials, metal powders, carbide powder, unwrought, waste and scrap, wrought wire, plate, sheet, strip, foil, other, oxides, calcium tungstate, other tungstates, other compounds	do.	5,650	62,700	5,070	69,100

See footnotes at end of table.

TABLE 8--Continued
U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS 1/

(Thousand metric tons and thousand dollars unless otherwise specified)

Mineral or product		1999 Quantity	1999 Value	2000 Quantity	2000 Value
Metals--Continued:					
Tungsten, tungsten content--Continued:					
Ores and concentrates	metric tons	2,870	12,400	2,370	11,100
Vanadium:					
Aluminum-vanadium master alloy, gross weight	kilograms	1,210,000	1,680	16,400	83
Ferrovanadium, vanadium content	do.	1,930,000	20,700	2,510,000	24,900
Metal, including waste and scrap, gross weight	do.	30,400	779	44,800	939
Miscellaneous chemicals, sulfates and vanadates, vanadium content	do.	174,000	1,650	149,000	1,070
Pentoxide, anhydride, vanadium content	do.	208,000	1,920	902,000	6,260
Vanadium-bearing ash, residues, slag from the manufacture of iron and steel, vanadium pentoxide content	do.	2,950,000	8,680	3,380,000	3,860
Other oxides and hydroxides, vanadium content	do.	--	--	13,500	231
Zinc:					
Compounds, lithopone, chloride, compounds n.s.p.f., hydrosulfite, oxide, sulfate	metric tons	78,700	75,800	87,400	83,800
Ore and concentrates, zinc content	do.	74,600	40,500	52,800	26,900
Rolled	do.	22,600	26,200	9,380	13,300
Slab, refined	do.	966,000	966,000	915,000	1,100,000
Zirconium and hafnium:					
Hafnium, unwrought, and waste and scrap	do.	9	1,770	11	2,240
Zirconium, ore and concentrates	do.	57,600	17,900	65,200	25,800
Zirconium oxide, includes germanium oxides and zirconium oxides	do.	3,140	27,800	3,950	35,000 e/
Zirconium, unwrought and waste and scrap	do.	859	46,700	1,040	52,700
Total		XX	45,700,000	XX	51,900,000
Industrial minerals:					
Abrasives, manufactured:					
Aluminum oxide, crude, ground and refined	metric tons	166,000	78,500	227,000	99,900
Boron carbide	do.	342	7,600	277	6,970
Metallic abrasives	do.	30,100	15,200 r/	33,500	17,600
Silicon carbide, crude, ground and refined	do.	169,000	79,500	190,000	94,300
Asbestos, chrysotile, crocidolite, other unspecified fibers	do.	15,800	3,150	14,600	2,510
Barite:					
Chemicals	do.	48,800	36,800	51,800	37,500
Crude	do.	836,000	43,500	2,070,000	92,400
Ground	do.	17,200	1,250	16,200	1,660
Other sulfates of	do.	17,500	14,300	15,400	14,000
Boron minerals and compounds:					
Borax		8	2,840	1	716
Boric acid		30	14,000	39	17,500
Colemanite		42	13,100	26	7,410
Ulexite		178	35,700	127	31,800
Bromine:					
Compounds, contained bromine	metric tons	7,140	31,200	14,500	31,100
Elemental	do.	1,970	2,110	5,470	3,730
Cement, hydraulic and clinker		29,400	1,140,000	28,700	1,070,000
Clays:					
Artifically activated clay and activated earth	metric tons	17,500	7,530	17,600	8,920
Bentonite	do.	8,930	2,990	8,470	2,930
Chamotte or dina's earth	do.	--	--	2	11
China clay or kaolin	do.	57,200	10,600	62,500	19,500
Common blue clay and other ball clay	do.	827	199	504	152
Decolorizing earths and fuller's earth	do.	398	19	70	12
Fire clay	do.	260	93	73	28
Other clay	do.	5,250	1,560	6,220	3,310
Diamond, industrial:					
Diamond stones, natural and miners'	thousand carats	3,130	14,300	2,520	13,400
Powder, dust and grit, natural and synthetic	do.	208,000	92,300	291,000	112,000
Diatomite	metric tons	387	332	529	316
Feldspar and nepheline syenite:					
Feldspar	do.	6,840	757	7,220	726
Nepheline syenite	do.	311,000	23,200	356,000	24,800

See footnotes at end of table.

r/ Revised. NA Not available. W Withheld to avoid disclosing company proprietary data; not included in "World" total. -- Zero.

1/ Data are rounded to no more than three significant digits.

2/ Content of ore and concentrate, unless otherwise specified.

3/ Gross weight.

4/ Individual country figures that are included in the world total represent dried bauxite equivalent of crude ore, but for some countries available data are insufficier to permit this adjustment.

5/ Does not include U.S. production.

6/ Includes rutile to avoid revealing company proprietary data. Rounded to one significant digit.

7/ Included with ilmenite to avoid revealing company proprietary data; not included in "World" total.

8/ Primary and secondary, unless otherwise specified.

9/ Primary.

10/ Includes bullion.

11/ Secondary production only. U.S. primary production is withheld to avoid disclosing company proprietary data.

12/ Refined nickel plus nickel content of ferronickel, nickel oxide, and other nickel salts.

13/ Includes tin content of alloys made directly from ore.

14/ Quantity sold or used by producers.

15/ Includes Puerto Rico.

16/ Shipments.

17/ Excludes, if any, U.S. production of low-quality sericite and sheet mica.

18/ Synthetic anhydrous ammonia; excludes coke oven byproduct ammonia.

19/ U.S. production is natural only.

20/ Data for the United States exclude proprietary pyrophyllite production.

MINING AND QUARRYING TRENDS

By Mary E. Ewell

Domestic survey data were prepared by the author and each of the statistical assistants who has responsibility for the commodities indicated.

The mining and quarrying trends shown in this report were calculated from nonfuel mineral data reported to the U.S. Geological Survey (USGS) by mining and quarrying companies operating in the United States. The data for 2000 were reported on the Mine, Development, and Mineral Exploration Supplement, a statistical survey conducted by the USGS, and on the production surveys for some more widely produced nonfuel mineral commodities, such as sand and gravel, for which the available data are extracted from computer files. Additional data for 2000 were derived from annual USGS production and consumption surveys of nonfuel mineral producers; these surveys covered 58 nonfuel mineral commodities produced in the United States.

Nonfuel minerals exclude coal, petroleum, coke, and related products.

As shown in this report, mining and quarrying data for 2000 include the annual data for construction sand and gravel and crushed and dimension stone. From 1981 to 1993, these mineral commodities were surveyed biennially and appeared alternately in this report. The inclusion of both sets of data in this report results in essentially a complete coverage of nonfuel mineral production in the United States. Comparisons of the 1994 to 2000 data with previously reported annual data, however, are not possible.

The data in the following tables are reported according to the primary product of a mine or operation. The primary product is usually determined by the product with the highest total value for the year. In some instances, the values of two products at the same operation are so close that the products are coproducts. To account for the data without double counting, however, a product of lesser value is considered to be a byproduct.

Total domestic mining of nonfuel mineral materials amounted to 5.4 billion metric tons (Gt) in 2000, about the same level as 1999. These materials included 4.0 Gt of crude ore mined or quarried and 1.4 Gt of mine waste and ore from development. Of the nonfuel mineral materials mined, 60% was for the production of industrial minerals and 40% was for the production of metals. Overall, 97% of nonfuel minerals was mined and quarried at surface level, and 3% was mined underground.

Total surface mining and quarrying for industrial minerals amounted to 3.2 Gt, remaining essentially the same as that of 1999. Crude ore mined at these surface operations was 2.8 Gt, and 355 million metric tons (Mt) was waste and ore from development. Underground mining for industrial minerals amounted to only 108 Mt, of which nearly all was crude ore.

Total surface mining for metal ores came to 2.1 Gt, slightly more than that of 1999. Of the 2.1 Gt, about 1.1 Gt was crude ore mined and the other 1.0 Gt was waste and ore from development. Underground mining of metal ores amounted to only 33 Mt, of which 97% was crude ore.

The major States in which mining for nonfuel minerals took place were, in order of total material handled, Nevada, Arizona, New Mexico, Minnesota, California, Florida, Texas, Michigan, Ohio, and Pennsylvania. These 10 States accounted for about 63% of the nonfuel minerals mined in the United States. Virtually all nonfuel mining in these States was conducted from the surface.

W Withheld to avoid disclosing company proprietary data; included with "Undistributed." -- Zero.

1/ Data are rounded to no more than three significant digits, except number of mines; may not add to totals shown.

2/ Includes materials from wells, ponds, and pumping operations.

3/ Includes solution mining.

4/ Includes quarries and other mineral operations.

5/ Includes ore and waste from development operations.

6/ Excludes materials from underground operations.

7/ Excludes waste from mining operations and ore and waste from development operations.

8/ Excludes materials from surface operations.

9/ Includes beryllium, copper, gold-silver, lead, magnesium metal, molybdenum, platinum and palladium, rare-earth metal concentrates, silver, titanium, uranium, and metals indicated by symbol W.

10/ Includes aplite.

11/ Excludes volcanic cinder and scoria; included with crushed and broken stone.

12/ Includes abrasives, boron minerals, bromine, diatomite, emery, greensand marl, iodine, iron oxide pigments, kyanite, lithium minerals, magnesite, olivine, perlite, potash, sericite, sulfur (Frasch), vermiculite, wollastonite, zeolites, and industrial minerals indicated by symbol W.

13/ Less than 1/2 unit.

14/ Includes States indicated by symbol W.

ABRASIVES, MANUFACTURED

By Donald W. Olson

Domestic survey data and tables were prepared by Christine K. Pisut, statistical assistant.

Abrasives play an important role in the fashioning and finishing of numerous products with a wide range of end-use applications. Abrasives are natural or manufactured substances that are used to abrade, clean, etch, grind, polish, scour, or otherwise remove solid material by rubbing action (as in a grinding wheel) or impact (as in pressure blasting). The most important physical properties for abrasives are hardness ("scratch" hardness), toughness (rigidity), friability, grain shape and size, character of fracture (cleavage), and purity (uniformity). Additional considerations include thermal stability, bonding characteristics, cost, and availability. Manufactured abrasives are made from metals or minerals by heating or chemically treating them to enhance or give them abrasive physical properties. No single property is paramount for any use (Wellborn, 1996, p. 31, 43).

Manufactured abrasives generally dominate high-grade abrasive markets as opposed to natural abrasives because they have superior physical properties and more uniform quality and can be tailored to meet user needs. Consequently, manufactured abrasives typically are characterized by premium prices relative to natural abrasive minerals. Even though manufactured abrasives are more expensive, their durability and efficiency have proven to be more cost-effective. Therefore, they are preferred in many industrial applications, such as metal finishing, cutting, and polishing.

This report includes information on the following abrasives: aluminum-zirconum oxide, boron carbide, fused aluminum oxide, metallic shot and grit, and silicon carbide. In some cases, United States production data were combined with Canadian output to protect proprietary information. Trade data in this report are from the U.S. Census Bureau. Quantities are reported in metric units unless otherwise noted.

Combined Canadian and United States production of aluminum oxide increased, while production of silicon carbide declined in 2000 from that of 1999. U.S. imports of crude, ground, and refined silicon carbide and of ground and refined aluminum oxide increased. U.S. metallic abrasives production decreased compared with that of 1999.

Fused Aluminum Oxide

Legislation and Government Programs.—As of January 1, 2000, the national defense stockpile (NDS) maintained by the U.S. Department of Defense (DOD) contained about 37,700 metric tons (t) of crude fused aluminum oxide valued at $7.3 million and about 17,700 t of fused aluminum oxide abrasive grain valued at $6.7 million. During 2000, the DOD reported sales of all NDS crude fused aluminum oxide for $8.7 million and sales of about 1,300 t of NDS aluminum oxide abrasive grain for $627,960. Under Federal legislation authorizing the disposal of all NDS aluminum oxide, the DOD plans to continue such sales until all the stockpiled aluminum oxide is sold (Janet Rollins, Market Analyst, Defense National Stockpile Center, oral commun., 2001). All the stockpiled aluminum

Manufactured Abrasives in the 20th Century

Silicon carbide was the first synthetic abrasive to be produced and the first to be commercialized. In 1891, the electric-furnace method for making silicon carbide was developed, beginning a revolution in the high-grade abrasives industry. Before that time, all abrasives were natural minerals and rocks, except for some minor use of chemically prepared materials. Silicon carbide was initially marketed under the trade name Carborundum. By 1900, U.S. production of Carborundum had already increased to about 1,200 metric tons with an estimated value of $263,000. Carborundum was mainly used by lapidaries in place of diamond powder, and as an abrasive material, it was made into hones and wheels. The only other manufactured abrasive in 1900 was crushed steel, for which domestic production was about 320 tons valued at $50,000. The largest part of the crushed steel production was used in the stonecutting trade, particularly for marble and granite. Very fine grades of crushed steel, also known as steel emery and rouge, were used by lens and other glass grinders.

By 2000, manufactured abrasives, with the exceptions of diamond and garnet, dominated the field of high-grade abrasives. Manufactured abrasives became essential to modern industry because they were more uniform in their properties and in their quality than most natural abrasives. The properties of manufactured abrasives can be varied to meet specialized needs. Most of the manufactured abrasives used in 2000 fell into one of the following categories: boron carbide, boron nitride, calcium and magnesium oxides, cerium oxide, chromium oxide, fused aluminum oxides, glass, iron oxides, magnesia, manufactured diamonds, metallic abrasives, porcelains or ceramics (which primarily used zirconium oxides or silicates), precipitated calcium carbonate, silicon carbide, sintered abrasives, sol-gel abrasives, and tin oxide. Manufactured abrasives included in this report are aluminum-zirconium oxide, boron carbide, fused aluminum oxide, metallic abrasives, and silicon carbide. Many of the other abrasives mentioned above are the subject of other U.S. Geological Survey mineral industry surveys. In 2000, the combined Canadian and United States production of abrasive aluminum oxide was estimated to be 90,000 tons with an estimated value of $29.4 million. The combined Canadian and United States production of silicon carbide was estimated to be 45,000 tons with an estimated value of $26.3 million.

Digitized by Google

oxide will be sold before 2004 if the current disposal and sales schedules continue.

Production.—The production data for fused aluminum oxide in this report were obtained by the U.S. Geological Survey (USGS) from producers in Canada and the United States. The data were collected from three companies that operated six plants and represented the entire Canadian and United States fused aluminum oxide industry (table 1). Two of the companies operated fused aluminum oxide plants in Canada and the United States. Data from the two countries were combined to protect company proprietary information.

Estimated production of regular-grade fused aluminum oxide in 2000 was 90,000 t with an estimated value of $29.4 million, an increase of about 6% by weight over the 1999 regular-grade fused aluminum oxide production (table 2). Reporting on the output of high-purity fused aluminum oxide has been discontinued to avoid disclosing company proprietary data.

Consumption.—Abrasive-grade fused aluminum oxide has many end uses. Specific applications in 2000 included bonded abrasives (such as abrasive grains that are made to adhere to each other and then are pressed or molded into abrasive tools), coated abrasives (such as abrasive grains glued to a backing of paper or cloth), tumbling media, air or water blasting media, polishing/buffing compounds, and antislip additives. The total value of fused aluminum oxide abrasive grain consumed in the United States was estimated to be $93 million in 2000.

Prices.—The USGS surveyed fused aluminum oxide producers to determine the total value of their production for the year. The survey indicated that the average unit value of regular fused aluminum oxide produced in the United States and Canada during 2000 was $331 per metric ton at the point of production; the average value of high-purity fused aluminum oxide output was $566 per ton at the point of production. Prices of abrasive grain produced from these materials and sold to consumers were significantly higher.

The average price of NDS crude fused aluminum oxide sold by the DOD in 2000 was $232 per ton. The average price of stockpiled fused aluminum oxide grain sold in 2000 was $483 per ton.

Average unit values of fused aluminum oxide trade by the United States in 2000 are based on U.S. Census Bureau customs value data. Average unit values of crude fused aluminum oxide imports during the year ranged from $179 per ton (China) to $447 per ton (Venezuela). Values of fused aluminum oxide grain imports ranged from $268 per ton (China) to $1,371 per ton (Austria). The average value for U.S. exports of fused aluminum oxide during the year was about $2,600 per ton.

Foreign Trade.—During 2000, imports of crude fused aluminum oxide were received from 8 countries and increased by about 21% to 110,000 t valued at $35.2 million compared with those of 1999, and imports of ground and refined fused aluminum oxide were received from 20 countries and increased by 57% to 117,000 t valued at $64.7 million (table 5). Some of the imported crude fused aluminum oxide was refractory-grade material. Canada, China, and Venezuela supplied 44%, 41%, and 15%, respectively, of the crude imports. China, Canada, and Austria provided 37%, 34%, and 9%, respectively, of the ground and refined material.

Compared with 1999 exports of all fused aluminum oxides, 2000 exports remained the same at 9,020 t, but the value of those exports increased to $23.5 million (table 6). Of the exports shipped to 29 countries, 76% went to Canada, Germany, Mexico, and the Netherlands.

Silicon Carbide

Legislation and Government Programs.—As of January 1, 2000, the NDS contained no more silicon carbide. Under congressional authority to dispose all NDS silicon carbide, the DOD sold the last portion of its stockpiled silicon carbide during the first quarter of 1999 (Janet Rollins, Market Analyst, Defense National Stockpile Center, oral commun., 2001). The DOD was not expected to replenish the silicon carbide stockpile.

Production.—Two companies produced abrasive-grade silicon carbide in Canada and the United States during 2000 (table 1). These companies also produced similar amounts of metallurgical-grade silicon carbide. Another company in Hopkinsville, KY, produced a small quantity of silicon carbide, primarily intended for use in heat-resistant products rather than abrasives. Table 2 lists estimated production rounded to avoid disclosing company proprietary information.

Consumption.—Abrasive-grade silicon carbide has many end uses. Specific applications in 2000 included antislip abrasives, blasting abrasives, bonded abrasives, coated abrasives, polishing/buffing compounds, tumbling media, and wiresawing abrasives. The total value of silicon carbide consumed in the United States was estimated to be about $111 million in 2000.

Prices.—The USGS does not collect price data on the various grades of silicon carbide. Based on information from industry sources and publications, however, the average value of abrasive-grade silicon carbide at the point of manufacture was estimated to be about $585 per ton in 2000.

During 2000, imports from China accounted for 82% of total U.S. crude silicon carbide imports and had an average value of $311 per ton; the average value of the remaining 18% of U.S. crude silicon carbide imports was $536 per ton. The average value of silicon carbide grain imports was $1,330 per ton; China accounted for 48% of such imports. The average value of total silicon carbide exports in 2000 was approximately $1,150 per ton.

Foreign Trade.—In 2000, the United States imported crude silicon carbide from 11 countries and imported ground or refined silicon carbide from 22 countries. Imports of crude silicon carbide increased by about 5% during the year to 162,000 t valued at $56.7 million (table 5). Imports of silicon carbide in ground or refined form increased by about 98% to 28,300 t valued at $37.6 million. China accounted for 82% of the crude silicon carbide imports and 48% of the ground or refined silicon carbide. A large part of the Chinese imports, however, reportedly included metallurgical-grade material.

During 2000, the United States exported crude silicon carbide to 15 countries and exported refined or ground silicon carbide to 26 countries. The total value of crude silicon carbide exports for 2000 increased by 13% to $2.78 million from the total value for 1999 (table 6). Compared with 1999 exports of refined or ground silicon carbide, 2000 exports increased by about 7% to 8,810 t valued at $8.71 million. Approximately 72% of the crude exports went to Mexico, and about 82% of the refined or ground material was shipped to Canada.

Aluminum-Zirconium Oxide

During 2000, fused aluminum-zirconium oxide for abrasive

Digitized by Google

applications (such as resin-bonded grinding wheels) was produced at two plants in Canada, one belonging to Norton Company (James Chenard, Senior Staff Accountant, Norton Company, oral commun., 2001) and one belonging to Washington Mills Electro Minerals Corp. (Martin Wozniak, Quality Assurance/Manufacturing Services Manager, Washington Mills Electro Minerals Corp., oral commun., 2001). The USGS does not publish aluminum-zirconium oxide production data received from the producers to avoid disclosing company proprietary information.

Boron Carbide

Only one firm, Washington Mills Electro Minerals Corp., was a commercial producer of boron carbide in the United States during 2000 (Martin Wozniak, Quality Assurance/ Manufacturing Services Manager, Washington Mills Electro Minerals Corp., oral commun., 2001). Boron carbide was used for grinding and lapping operations previously possible only with diamond dust; it also was molded to form highly wear-resistant products, such as pressure blast nozzle liners and extrusion dies.

Domestic production data for boron carbide are not reported here to avoid disclosing company proprietary information. The following trade information on boron carbide, however, was available: the United States imported 277 t of boron carbide valued at $6.97 million from 5 countries, primarily Germany, China, and Japan, and exported 28.6 t valued at $481,000 to 12 nations in 2000 (U.S. International Trade Commission, [undated], HTS-2849901000—Customs value by customs value for all countries, accessed July 9, 2001, via URL http://dataweb.usitc.gov/scripts/user_set.asp).

Metallic Abrasives

Production.—Data on U.S. production and shipments of metallic abrasives were based on a survey of domestic producers conducted by the USGS. Survey data were collected from 12 companies operating 14 plants in the United States and accounted for all the domestic industry (table 3).

Steel shot and grit account for almost all metallic abrasives produced domestically (table 4). U.S. production of steel shot and grit in 2000 decreased slightly compared with that of 1999; the average value per ton was $444. Six companies reported production of cut wire shot in 2000, and most of that was cut from carbon steel wire and stainless steel wire. Other products reported included shot cut from aluminum, copper, and zinc wire.

Consumption.—Metal abrasives are used primarily as loose particles propelled at high velocities for blast cleaning or to improve the properties of metal surfaces; approximately 75% of the abrasives are employed in cleaning operations. Principal consumers include foundries, steel manufacturers, machine tool industries, and metalworking plants, particularly those supporting the automotive and aircraft industries.

During 2000, total sales of all steel shot and grit by U.S. producers decreased slightly compared with shipments in the preceding year, and the average value per ton sold or used decreased slightly to $449.

Prices.—The USGS compiles survey data on the value of production and shipments, but it does not collect price data. Values of production and shipments reported by metallic abrasive producers in 2000 are listed in table 4. Values of steel shot and grit were estimated to be from $0.35 to $0.50 per kilogram in 2000. Estimated average values of cut wire shot in 2000 were $3.65 to $5.15 per kilogram for aluminum wire shot and $2.65 to $5.15 per kilogram for stainless steel wire shot.

Average unit values for metallic abrasives traded by the United States during 1999 were as follows: exports averaged $0.64 per kilogram, and imports averaged $0.52 per kilogram.

Foreign Trade.—During 2000, the United States imported metallic abrasives from 18 countries and exported metallic abrasives to 38 countries. Domestic imports increased by about 11% in 2000 to 33,500 t valued at $17.6 million (table 5). About 68% of the imports came from Canada; most of the remaining imports were shipped from the United Kingdom, France, and Germany.

U.S. exports of metallic abrasives increased by about 9% during the year to 28,900 t valued at $18.6 million (table 6). Most of the exports went to Canada; most of the remainder was shipped to Mexico, the United Kingdom, Japan, and Belgium.

Outlook

Economic and technological trends will most likely continue to influence the manufacturing of abrasive materials in the United States. Cheaper imports and higher domestic costs will challenge U.S. producers of fused aluminum oxide and silicon carbide. Competition from developing nations, such as China, will continue to lead to decreases in domestic output. The traditional suppliers among the Western industrialized nations are expected to continue consolidating and contracting.

Metal abrasives markets will continue to be influenced by improved technology in industries that use metallic abrasives. For example, better metal casting methods that achieve near-finish surfaces will reduce demand for some abrasives. Lesser quantities of metallic abrasives will be needed in foundries where new chemical cleaning and finishing techniques are employed.

Emerging suppliers of fused aluminum oxide and silicon carbide in China, Eastern Europe, India, the Republic of Korea, and South America will continue to increase their prominence in world markets. Further success for these suppliers, particularly in such major markets as Japan, the United States, and Western Europe, will depend on their ability to provide higher grades of material and the level of supply reliability while maintaining lower prices. Energy costs, furnace size, quality-control systems, and the availability of essential mineral inputs will be the dominant factors influencing the competitive stance of these suppliers (O'Driscoll, 1997; Zhilun, 1997; Lunghofer and Wolfe, 1998).

Motor vehicle manufacturing will remain a significant indirect influence on demand for manufactured abrasives used by metalworking operations supporting the industry. Curbs on metals consumption by the industry, such as substitution by plastics and newer lighter weight designs of automobiles, are important factors to be considered in long-range demand forecasts for manufactured abrasives.

ALUMINUM

By Patricia A. Plunkert

Domestic survey data and tables were prepared by Micheal George, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

In 2000, 12 domestic companies operated 23 primary aluminum reduction plants that produced almost 3.7 million metric tons (Mt) of metal. Montana, Oregon, and Washington accounted for 36% of the production; Maryland, New York, Ohio, and West Virginia, 22%; and other States, 42%. The value was estimated to be $6 billion.

Increased energy costs, particularly in the Pacific Northwest, led several aluminum smelters to reduce production capacity during the latter half of the year. By yearend, a total of 729,000 tons per year (t/yr) of primary smelter capacity had been closed, about 45% of the 1.62 million tons per year (Mt/yr) of engineered capacity for the 10 smelters operating in the region.

Aluminum recovered from purchased scrap decreased by 7% to 3.45 Mt. Of this recovered metal, 60% came from new (manufacturing) scrap and 40% from old (discarded aluminum products) scrap. Aluminum used beverage can (UBC) scrap accounted for more than one-half of the reported old scrap consumption in 2000. The recycling rate for aluminum UBCs remained relatively stable at 62.1%.

The transportation and the container and packaging industries remained the largest domestic markets for aluminum products in 2000. The transportation industry accounted for 37% of domestic consumption; containers and packaging, 23%; building and construction, 15%; consumer durables, 8%; electrical, 8%; and other uses, 9%.

U.S. imports for consumption decreased in 2000 compared with those of 1999, reversing a 3-year upward trend that began in 1997. Canada remained the largest shipper of aluminum materials to the United States, followed by Russia. Total exports from the United States increased 7% in 2000.

The price of primary ingot on the domestic and the international markets fluctuated during the year. The 2000 monthly average domestic price decreased by almost 6 cents per pound from January to December. The annual average, however, increased compared with that of the previous year.

At the end of 2000, world inventories, as reported by the International Aluminium Institute (IAI), decreased slightly compared with those of 1999. Inventories of primary metal held by the London Metal Exchange Ltd. (LME) decreased dramatically, whereas inventories of aluminum alloy increased.

Primary aluminum was produced in 43 countries in 2000. The United States remained the largest producer with 15% of the world total, followed by Russia with 14%, China with an estimated 11%, and Canada with 10%. World primary metal production increased by about 2% compared with that of 1999.

Production

Primary.—Domestic primary aluminum production, which totaled a reported 3,668,438 metric tons (t), decreased by 3% compared with that of 1999 (table 1). Production data were obtained from the 12 domestic producers, all of whom responded to the request from the U.S. Geological Survey (USGS) for data.

On May 3, 2000, Alcoa Inc. and Reynolds Metals Co. announced that the U.S. Department of Justice (DOJ) and the European Union (EU) had approved their proposed merger and that the merger had been completed. Reynolds shareholders had

Aluminum in the 20th Century

Aluminum is the second most abundant metallic element in the earth's crust after silicon, yet it is a comparatively new industrial metal that has been produced in commercial quantities for just over 100 years. In April 1886, a formal patent application was filed that permitted, for the first time, the mass commercial production of aluminum. In 1900, the Pittsburgh Reduction Company (Alcoa Inc.) was the sole domestic producer of primary aluminum metal, and production had grown to 3,244 metric tons (7.15 million pounds) from 83 pounds in 1883. World production in 1900 totaled 7,339 tons and took place at nine reduction plants owned by six companies in four countries. The United States was the leading producer, followed by Switzerland (2,500 tons), France (1,026 tons), and the United Kingdom (569 tons). The metal was used mainly as a substitute for copper in the transmission of electricity and for culinary articles, machinery parts, special alloys, explosives, paint, and as a substitute for stone and zinc in lithographic work.

In 2000, the United States remained the world's largest producer and consumer of aluminum; however, its dominance in the industry had eroded over the last 40 years of the century. At the close of World War II, domestic primary aluminum production accounted for over 40% of the world's production. In 2000, primary aluminum was produced in 43 countries, and the United States accounted for only about 15% of the 24 million tons of production. Since the inception of the aluminum industry, metal has been recovered from scrap and its importance as a source of aluminum supply continues to grow. In 2000, metal recovered from scrap accounted for about 35% of the domestic supply of aluminum. Energy costs and concerns over waste management will continue to provide the impetus for increased recycling rates. Today, aluminum is used in a wide range of applications, such as automobiles, airplanes, buildings, tools, appliances, packaging, electrical systems, and countless other components of everyday life. Measured either in quantity or value, aluminum's use exceeds that of any other metal except steel, and it is important in virtually all segments of the world economy.

Digitized by Google

approved the merger on February 11. Under the terms of the consent decree entered into with the DOJ and an undertaking agreement with the EU, Alcoa was forced to sell a 25% interest in Reynolds' Longview, WA, smelter, as well as Reynolds' interests in three alumina refineries—Worsley, Australia (56%); Stade, Germany (50%); and Sherwin, TX (100%). As a result of the merger, each outstanding share of Reynolds common stock was converted into 1.06 shares of Alcoa common stock (Alcoa Inc., 2000g).

On June 1, Alcan Aluminium Ltd. and algroup, the aluminum division of Alusuisse Lonza Group Inc., announced that, following the approval of the DOJ and the EU, the companies had reached agreement on their merger plan (Alcan Aluminium Ltd., 2000a). The EU gave its approval subject to commitments made by the companies to alleviate the EU's competition concerns in the aluminium trihydrate (ATH) market. Among its commitments, Alcan proposed selling algroup's ATH facility in Martinswerk, Germany, and the algroup lithography operations in Bridgenorth, United Kingdom (Platt's Metals Week, 2000j). The merger, which involved the combination of a cash payment and the exchange of 17.1 Alcan common shares for every algroup share, was finalized on October 17 (Alcan Aluminium Ltd., 2000h).

Increased energy costs, particularly in the Pacific Northwest, led several aluminum smelters to reduce production capacity during the latter half of the year. By yearend, a total of 729,000 t/yr of primary smelter capacity had been closed, about 45% of the 1.62 Mt/yr of engineered capacity for the 10 smelters operating in the region. Columbia Falls Aluminum Co. had idled two and one-half of its five potlines at its 168,000-t/yr Columbia Falls, MT, smelter and temporarily reduced production capacity by 84,000 t/yr (Metal Bulletin, 2000i). Northwest Aluminum Corp. closed its 82,000-t/yr smelter in The Dalles, OR (Metal Bulletin, 2000j). Goldendale Aluminum Co. idled all but 25,000 t/yr of capacity at its 168,000-t/yr smelter in Goldendale, WA (Metal Bulletin, 2000j). Kaiser Aluminum & Chemical Corp. closed its 73,000-t/yr Tacoma, WA, smelter and idled 110,000 t/yr of capacity at its 200,000-t/yr smelter in Spokane (Mead), WA (Kaiser Aluminum & Chemical Corp., 2000b). Alcoa temporarily idled its 121,000-t/yr smelter in Troutdale, OR (Alcoa Inc., 2000j), and Vanalco Inc. idled its 116,000-t/yr smelter in Vancouver, WA (Metal Bulletin, 2000v).

In June, Ormet Primary Aluminum Corp. temporarily closed two potlines at its 257,000-t/yr smelter in Hannibal, OH, resulting in a loss of 7,000 metric tons per month (t/mo) of aluminum metal production. The decision to close was based on low aluminum prices, higher than usual alumina prices, and higher electrical energy prices in the peak summer months. During the closure, the company sold its excess alumina and electricity (Ormet Primary Aluminum Corp., 2000b). In August, Ormet announced the restart of the two idled potlines, which were back in operation by the end of September (Ormet Primary Aluminum Corp., 2000a).

Alcan restarted 60,000 t/yr of capacity at its 186,000-t/yr primary aluminum smelter in Sebree, KY, to meet increased customer demand and to compensate for smelter closures in Canada and the United Kingdom. The restart was completed by yearend (Alcan Aluminium Ltd., 2000f).

In January, Alcoa announced plans to restart 200,000 t/yr of primary aluminum smelter capacity by the end of the year. The restarts would be spread over the 450,000-t/yr of capacity that had been idled since 1994 and was expected to involve low-cost, operating smelters in the United States and Australia (Alcoa Inc., 2000k).

Alcoa and Michigan Avenue Partners (MAP) announced that they had reached an agreement whereby MAP would acquire the 204,000-t/yr aluminum smelter in Longview, WA. Alcoa was required to sell 25% of Longview as a condition of the EU approval of the Alcoa/Reynolds merger, but Alcoa accepted MAP's offer to purchase the entire operation. MAP is a Chicago investment group. One of its affiliates, McCook Metals L.L.C. is the second largest aluminum plate company in North America and produces specialty products for aircraft, aerospace, and defense industries. The sale was contingent on financing and regulatory approval (Alcoa Inc., 2000m).

Century Aluminum Co. purchased Xstrata AG's 23% interest in the 215,000-t/yr Mount Holly, SC, primary aluminum smelter. The $95 million purchases increased Century Aluminum's interest in the smelter to 49.67%. Alcoa, which owned 50.33% of the smelter, will continue to operate and manage the facility (Regan, 2000a).

Century Aluminum and Southwire Co. reached a definitive agreement for the purchase of Southwire's 237,000-t/yr smelter in Hawesville, KY. Completion of the $468 million transaction was subject to the completion of a labor agreement, arrangement of financing, and the receipt of regulatory approvals (Southwire Co., 2000).

Noranda Aluminum Inc. commissioned its new single-piece anode process at its 222,000-t/yr aluminum smelter in New Madrid, MO. Completion of the $72 million expansion, which was expected by mid-2002, will increase production capacity at the smelter by 15% to 253,000 t/yr (Platt's Metals Week, 2000o).

Alcan revealed plans for a $22 million capital project to expand extrusion billet production at its Sebree, KY, aluminum smelter by 65,000 t/yr. The project, which was begun in August and would require approximately 20 months to complete, involved engineering work and construction of an ultrasonic billet inspection station, a new continuous homogenization furnace, as well as an automated billet sawing and stacking system (Alcan Aluminium Ltd., 2000c).

Ormet announced that it planned to curtail carbon anode operations at its Hannibal smelter by the end of September 2001. The company reported that the closure was primarily in response to the Maximum Achievable Control Technology requirements, as established under the provisions of the Clean Air Act, that were due to take effect at their smelter in October 2001. Ormet's decision not to modernize the facility to meet the new environmental standards was owing to the age and configuration of the facility and the potential development of advanced technology. The company was negotiating with outside suppliers for the purchase of its 170,000-t/yr carbon anode requirement. The purchased anodes, which would be larger than those produced by Ormet, reportedly would allow increased metal production without the consumption of additional power (Ormet Primary Aluminum Corp., 2000c).

In May, members of United Steelworkers of America (USWA) Local 5724, which represents 1,200 employees at Ormet's Hannibal, OH, smelter, ratified a new labor agreement. Terms of the contract, which was set to expire at the end of August 2003, were not disclosed (Regan, 2000b).

Century Aluminum and the USWA reached agreement on a new 5-year labor contract at the Hawesville, KY, primary

Digitized by Google

aluminum smelter. Terms of the agreement, which will become effective upon completion of the purchase of the smelter, were not disclosed (Metal Bulletin, 2000h).

A labor dispute between the USWA and Kaiser, which began in September 1998, officially ended on September 18 when an arbitration panel ruled on a half-dozen unresolved issues that were blocking completion of a new contract. The new contract runs through September 30, 2005, calls for a 2.6% average annual increase in the overall wage and benefit package, and reduces the total number of hourly jobs by approximately 19% at the five plants covered by the contract (Kaiser Aluminum & Chemical Corp., 2000a).

MAP and USWA ratified a new 5-year labor contract covering workers at the Scottsboro, AL, rolling mill. The contract included increases in wages, pensions, retiree medical benefits, and enhanced opportunities to share in productivity gains. The mill produces about 136,000 t/yr (300 million pounds per year) of mill-finished and painted sheet products (Metal Bulletin, 2000t).

Alcan announced that it was investing $15 million at its Terre Haute, IN, light gauge rolling facility. The project, which ultimately would increase the plant's capacity by about 22,700 t/yr (50 million pounds per year), included a wide foil mill with doubling capability to complement existing rolling equipment. The facility produces light gauge aluminum fin and foil products (Alcan Aluminium Ltd., 2000g).

Kaiser completed the sale of its Micromill® assets and patented technology to Alcoa for an undisclosed price. The Micromill process is a continuous casting technology developed by Kaiser in the early 1990s, which was designed to convert molten metal into aluminum sheet in a single continuous step. The prototype plant built in Reno, NV, a key element of the sale to Alcoa along with all patent rights to the technology, was designed to produce 41,000 t/yr (90 million pounds per year) of flat rolled aluminum (Metal Bulletin, 2000c).

Commonwealth Industries Inc. announced that its subsidiary, Commonwealth Aluminum Corp., signed a 10-year guaranteed supply agreement with Glencore Ltd. for the purchase of primary aluminum. Commonwealth agreed to purchase a minimum of 544,000 t (1.2 billion pounds) of aluminum beginning January 1, 2001. This purchase will fill only part of Commonwealth's metal requirements for its fabrication facilities. Commonwealth Aluminum is a large recycler of aluminum, and more than one-half of its raw material comes from scrap (Commonwealth Industries Inc., 2000).

McCook Metals, a subsidiary of MAP, entered the aluminum extrusion market. The company began casting 2000, 6000, and 7000 series extrusion billets at its rolling mill in McCook, IL. Depending on the alloy, the plant uses scrap and/or primary metal to make the billets (Platt's Metals Week, 2000l).

Norsk Hydro ASA purchased Wells Aluminum Corp., a major U.S. extrusion company based in Baltimore, MD. The acquisition will increase Hydro's extrusion capacity by 75,000 t/yr and, according to the company, will make it the fourth largest extrusion company in the United States with a potential sales volume of 110,000 t/yr. Wells was a custom extruder, finisher, and fabricator of soft alloy aluminum products principally serving the building and construction, transportation, consumer durables, and electrical markets. Wells had a network of 7 facilities with 12 extrusion presses in 6 Midwestern and Southeastern States plus its own casting facility for extrusion billet (Norsk Hydro ASA, 2000b).

Alcoa purchased Excel Extrusions Inc., a subsidiary of Noranda Aluminum Inc. Excel's plant in Warren, OH, has the capacity to produce about 16,000 t/yr (35 million pounds per year) of soft alloy aluminum extrusions, which are used primarily in the building and construction industries. The plant also has a vertical paint line with a capacity to coat about 11,000 t/yr (24 million pounds per year) of extrusions (Alcoa Inc., 2000h).

Butler Manufacturing Co. announced plans to build a new aluminum extrusion and finishing plant in Greeneville, TN, for its Vistawall Architectural Products division, a manufacturer of engineered windows, curtain walls, storefront and skylight systems for the nonresidential building construction market (Butler Manufacturing Co., 2000). The plant initially will add 9,000 t/yr (20 million pounds per year) of capacity, increasing the company's extrusion capacity by 50% (Platt's Metals Week, 2000f).

Indalex Aluminum Solutions Group, a subsidiary of Caradon plc of the United Kingdom, underwent some major changes during the year. Indalex acquired the aluminum extrusion and billet casting operations of Columbia Pacific Aluminum Corp., a subsidiary of Columbia Ventures Corp. The purchase included casting plants in City of Industry, CA, and Rockwall, TX, as well as three extrusion plants in California—Modesto, Watsonville, and City of Industry (Platt's Metals Week, 2000h). Indalex closed two of its older extrusion facilities in Dolton, IL, and Winton, NC (Platt's Metals Week, 2000k). The company also launched several expansion plans. Indalex announced plans to build a new 79,000-t/yr (175-million-pound-per-year) casting facility in Toronto, Canada. The plant will become part of Indalloy, the casting division of Indalex (Indalex Aluminum Solutions Group, 2000b). Expansion plans for existing facilities were also announced. Indalex planned to invest $42 million during 2001 to improve and expand its facilities in Gainesville, GA; Elkhart, IN; and Toronto, Canada (Indalex Aluminum Solutions Group, 2000a).

Quanex Corp. purchased Temroc Metals Inc., an aluminum extrusion and fabrication company based in Hamel, MN, which produced customized aluminum extrusions and fabricated metal products for recreational vehicles, architectural products, electronics, and other markets (American Metal Market, 2000f).

Alcoa announced plans to begin construction of a new cast aluminum rod production facility in early 2001. The facility will produce cast rod in sizes tailored to forged and impact-extruded applications in the automotive, industrial, and consumer markets, and will increase the availability of standard and special rod and bar, standard and custom profiles, seamless and structural pipe and tube, and drawn seamless tube (Alcoa Inc., 2000i).

Alcoa acquired Cordant Technologies Inc. Cordant was composed of three business units: Howmet Castings, a supplier of investment cast superalloy and titanium components used in jet aircraft and electrical power generation; Huck Fasteners, a designer and manufacturer of high-performance fasteners and fastening systems; and Thiokol Propulsions, a supplier of solid rocket propulsion systems. Cordant had approximately 17,000 employees worldwide at some 58 facilities in Canada, France, Japan, the United Kingdom, and the United States (Alcoa Inc., 2000e). With the purchase of Cordant, Alcoa acquired 84.7% of Howmet International Inc. By the end of June, Alcoa had purchased all of the outstanding shares of Howmet and became the company's sole owner (Alcoa Inc., 2000f).

Digitized by Google

Alcoa also purchased the assets of privately held C-KOE Aluminum Inc. of Dallas, TX. C-KOE Aluminum produced primary grade aluminum particle ingot for the chemicals and metals markets (Alcoa Inc., 2000b).

Secondary.—Metal recovered from new and old scrap decreased to 3.45 Mt in 2000 (table 3), according to data derived by the USGS from its "Aluminum Scrap" survey. Of the 78 companies and/or plants to which monthly or annual survey requests were sent, 57 responded, which represented 91% of the total scrap consumed, as listed in table 4.

According to figures released by the Aluminum Association Inc., the Can Manufacturers Institute and the Institute of Scrap Recycling Industries Inc., 62.6 billion aluminum UBCs were recycled in the United States in 2000, for a beverage can recycling rate of 62.1% or nearly two of every three aluminum cans shipped. Although the recycling rate was slightly lower than the 1999 rate of 62.5%, this was the 12th consecutive year that the U.S. recycling rate exceeded 60%. According to the organizations, the average aluminum beverage can produced domestically is comprised of more than 51% recycled content (Aluminum Association Inc., 2001a).

Superior Aluminum Alloys installed a third furnace at its New Haven, IN, facility increasing the plant's capacity by 42%. The plant's capacity will increase to about 8,000 t/mo (17 million to 18 million pounds per month) or more than 90,000 t/yr. The company also installed an automatic sow-casting system, which will enable it to pour up to one sow per minute (Platt's Metals Week, 2000p).

Behr Metals, a subsidiary of Joseph Behr & Sons, also installed a new furnace at its facility that doubled the plant's smelting capacity. A new 102-t (225,000-pound) furnace was installed at the company's Rockford, IL, plant and was expected to produce about 3,000 t (7 million pounds) of metal per month (Metal Bulletin, 2000f).

Alcan's extrusion scrap recycling facility in Sebree, KY, started up during the latter half of the year. The feed for this plant was expected to be new extrusion scrap, most of which would be generated by Alcan's customers. The furnace has an capacity of 50,000 t/yr (Platt's Metals Week, 2000b).

In October, Norsk Hydro's new remelt plant in Henderson, KY, came on-stream with an initial capacity of 90,000 t/yr of extrusions. The plant will recycle aluminum scrap into primary quality aluminum extrusion billets (Norsk Hydro ASA, 2001a, p. 21).

Wabash Alloys LLC closed 25% of its capacity at its East Syracuse, NY, plant. Prior to the cutback, the plant had a capacity of about 7,000 t/mo (15 million pounds per month) (Worden, 2000c).

Huron Valley Steel Corp. closed its 27,000-t/yr (60-million-pound-per-year) River Rouge, MI, smelter. The facility, known as Fritz Products, produced specification ingot, such as A380.1, from shredded aluminum scrap provided by Huron Valley. In lieu of operating the smelter, the company will concentrate on improving the quality of and expanding the markets for shredded aluminum products based on recent improvement in their aluminum particle sorting technologies. Longer-term plans called for upgrading and reopening the River Rouge smelter (Worden, 2000c).

Keystone Aluminum Inc. reportedly closed its secondary smelter in Mars, PA. The plant produced aluminum deox for the steel industry (Worden, 2000a).

In December, Alchem Aluminum Inc., a wholly owned subsidiary of IMCO Recycling Inc., began operations at its new 91,000-t/yr smelter in Saginaw County, MI, that will supply General Motors Corp. (GM) with more than 900,000 t (2 billion pounds) of specification aluminum alloys over a 13-year period. All of the production from this plant will be delivered in molten form to GM's Saginaw metal casting operation to manufacture engine components (IMCO Recycling Inc., 2001a, p. 3, 6).

Quanex purchased a continuous cast rolling mill in Ft. Lupton, CO, from Alcoa. In August 1999, Alcoa purchased the Ft. Lupton and the San Antonio, TX, rolling mills from ACX Technologies Inc. Both of the plants converted UBCs to can sheet. Upon reviewing the Alcoa purchase, the DOJ determined that the acquisition of the Ft. Lupton facility would likely lessen competition in the manufacture and sale of can lid stock since Alcoa controlled 50% of the North American market and Ft. Lupton was one of only five other North American producers. Therefore, to avoid antitrust violations, Alcoa was required to sell the facility and upon its purchase, Quanex was required to continue to operate the plant in the manufacture and sale of can lid stock (Platt's Metals Week, 2000m).

IMCO closed its Sikeston, MO, and Bedford, IN, aluminum recycling plants. The material processed at these plants will be handled at other IMCO facilities and most of the plants' equipment will be sent to other plants (IMCO Recycling Inc., 2000). The closure of the Bedford and Sikeston plants reportedly reduced IMCO's domestic annual capacity by about 10% or 122,000 t (270 million pounds) (IMCO Recycling Inc., 2001b). IMCO also temporarily closed its Wendover, UT, plant that normally recycled aluminum dross (IMCO Recycling Inc., 2001a, p. 8).

Consumption

In 2000, the transportation industry accounted for slightly more than 3.6 Mt of total U.S. shipments of aluminum products (table 6). Shipments to the container and packaging industry, which was the second largest domestic end-use market, continued to decline and was less than 2.3 Mt. Total shipments of aluminum products to domestic users in 2000 was at the same level as that of 1999.

The Partnership for a New Generation of Vehicles (PNGV), initiated in 1993, represents a historic and unprecedented collaboration among teams of scientists and engineers from the U.S. automotive industry, the Federal Government, and academia. One of the goals of the PNGV is the development of family car prototypes that will get nearly three times the Corporate Average Fuel Economy (CAFE) Federal regulatory requirement of 27.5 miles per gallon. At the North American International Auto Show, held in January, Ford Motor Co. and GM introduced their prototypes to the public. Both the GM Prodigy and the Ford Precept were reported to be aluminum intensive vehicles that would use aluminum for the frame and body panels (Wrigley, 2000d). Meanwhile, the use of aluminum in the typical family vehicle continued to grow from 75 kilograms (kg) (166 pounds) in 1991 to more than 111 kg (245 pounds) in 2000 (Wrigley, 2000f).

DaimlerChrysler Corp. announced that it planned to purchase the major components for its new cross-mounted V-6 engines from Nemak SA, Monterrey, Mexico. When engine production begins in 2002, the block and head castings are expected to use more than 14,000 t (31 million pounds) of recycled aluminum annually (Wrigley, 2000g). Later in the year, GM announced

Digitized by Google

that it would purchase, on an annual basis, aluminum cylinder head castings from Nemak for up to 350,000 of its Gen III Vortec V-8 truck engines. Nemak's 7,300 t/yr (16 million pounds per year) of head castings would supplement the castings already being provided by GM's own casting operations in Saginaw, MI, and Castech SA's facilities in Saltillo, Mexico (Wrigley, 2000c).

Ford opened a new aluminum casting plant in Brook Park, OH, to produce engine blocks for its new 2.3 liter, in-line four-cylinder engine. Initial production at the plant was expected to be about 110,000 aluminum engine blocks per year. Precision sand casting will be used to produce the engine blocks (Wrigley, 2000b). In November, Ford and Nemak signed an agreement giving Nemak control of Ford's two big aluminum parts-casting plants in Ontario, Canada, the Windsor Aluminum Plant and the Essex Aluminum Plant. These two plants consume enough secondary aluminum alloy to produce an estimated 81,600 t (180 million pounds) of engine castings each year (Wrigley, 2000a).

Alcan and Ford signed a multiyear aluminum supply agreement. Alcan will provide metal in various forms, including foundry ingot for cast products and flat-rolled autobody sheet for Ford's stamping plants. Alcan will also provide design and technology support services, and Ford will purchase minimum monthly volumes of metal with options for additional amounts as required (Alcan Aluminium Ltd., 2000b).

Anticipating a major increase for aluminium suspension system components in the automotive market, Hayes Lemmerz International Inc. announced plans to build a new foundry in Montague, MI. The plant reportedly would use primary aluminum casting alloys to produce control arms, knuckles, crossmembers, and other components for the North American automotive industry (Wrigley, 2000e).

Pechiney sold its remaining interest in American National Can Group (ANC) to Rexam plc of the United Kingdom. With can plants elsewhere in Europe, the addition of ANC's 38 billion beverage cans per year gives Rexam an annual canmaking capacity of 45 billion cans and makes the company the world's largest can manufacturer (Metal Bulletin, 2000q).

Ball Corp., a metal and plastic packaging supplier, announced several plant closures during the year. Ball's Salisbury, NC, aluminum beverage can plant, which had the capacity to produce about 1 billion cans per year, was closed during the third quarter. Ball also announced that it had halted a previous owner's plans to install a beverage can line in a plant in China and had written off a 10% stake in a Russian beverage can joint venture (Platt's Metals Week, 2000d). Ball closed a two-piece aluminum beverage can manufacturing line at its Richmond, British Columbia, plant, and a metal coating and sheeting operation at its Hamilton, Ontario, facility was expected to close by March 2001 (American Metal Market, 2000c).

Crown Cork & Seal reported the reorganization of its U.S. metal packaging units from a single business unit into three divisions—beverage cans, food cans, and aerosol cans. The breakup would give the company the flexibility to sell or joint venture the individual divisions (Platt's Metals Week, 2000i).

Stocks

Domestic inventories of aluminum ingot, mill products, and scrap decreased to 1.55 Mt at yearend 2000 from 1.87 Mt at yearend 1999 (Aluminum Association Inc., 2001b). The LME reported that primary aluminum metal ingot at its U.S. warehouses decreased dramatically to 125 t at yearend 2000 from 12,700 t at yearend 1999. The LME also reported that at yearend 2000 its U.S. warehouses did not hold any stocks of aluminum alloy ingot compared with 860 t at yearend 1999 (London Metal Exchange Ltd., 2000).

Prices

The monthly average U.S. market price of primary aluminum metal, as reported by Platt's Metals Week, fluctuated throughout the year. The monthly average price began the year at 80.1 cents per pound and, by December, had fallen to 74.3 cents per pound. However, the average price for the year increased from 65.7 cents per pound in 1999 to 74.6 cents per pound in 2000.

The LME cash price for high-grade primary aluminum ingot followed the same general trend as the U.S. market price. The 2000 average annual LME cash price was 70.3 cents per pound.

In May 1999, the Commodity Exchange (COMEX) division of the New York Mercantile Exchange (NYMEX) launched an aluminum futures contract for primary aluminum ingot. During its first full year of trading, the average monthly spot settlement price followed the trend of both the U.S. market and LME prices. The monthly average, based on a rolling average of the daily spot settlement price, declined from 80.3 cents per pound in January to 74.6 cents per pound in December.

Purchase prices for aluminum scrap, as quoted by American Metal Market, also fluctuated during the year but closed at lower levels than those at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 47.5 to 48.5 cents per pound; old sheet and cast aluminum, 38.5 to 39.5 cents per pound; and clean, dry aluminum turnings, 40 to 41 cents per pound.

Aluminum producers' buying price range for processed and delivered UBCs, as quoted by American Metal Market, also closed lower at yearend. The price range began the year at 57 to 59 cents per pound and closed the year at 53 to 54 cents per pound. Resource Recycling published a monthly transaction price for aluminum UBCs in its Container Recycling Report. During the year, the monthly average decreased significantly from 62.9 cents per pound in January to 53.9 cents per pound in December. However, similar to the U.S. market price trend of primary aluminum ingot, the annual average price for aluminum UBCs in 2000 of 57.7 cents per pound was higher than the 1999 annual average of 50.6 cents per pound.

The yearend indicator prices for selected secondary aluminum ingots, as published in American Metal Market, also decreased significantly compared with those of 1999. The closing prices for 2000 were as follows: alloy 380 (1% zinc content), 68.7 cents per pound; alloy 360 (0.6% copper content), 74.1 cents per pound; alloy 413 (0.6% copper content), 73.8 cents per pound; and alloy 319, 72.7 cents per pound. Platt's Metals Week published an annual average U.S. price of 65.6 cents per pound for A-380 alloy (3% zinc content). The average LME cash price for a similar 380 alloy was 55.2 cents per pound.

Trade

Total exports of aluminum materials from the United States increased 7% in 2000 compared with those of 1999 (table 8).

Digitized by Google

Exports of semifabricated material and scrap increased but exports of crude metals and alloys decreased compared with those of 1999 (table 9). About two-thirds of total U.S. exports were accounted for by Canada and Mexico.

Imports for consumption decreased in 2000 compared with those of 1999, reversing a 3-year upward trend that began in 1997 (table 10). Canada remained the major source country by supplying 55% of the total imports in 2000 (table 11). Russia continued to be the second largest supplier of aluminum materials. The decline in imports of crude metal and alloys from Russia was more than compensated for by increased imports of semifabricated materials and scrap.

World Review

Despite the temporary closure of production capacity in the Pacific Northwest region of the United States, world production of primary aluminum metal increased by 2% in 2000 compared with that of 1999 (table 12). Production increased owing in part to the opening of new smelters in Canada and Mozambique. U.S. and Asian demand was weak, especially during the latter half of the year, whereas European demand was reported to be steady.

Unwrought aluminum inventories held by members of the IAI decreased slightly to 1.79 Mt at yearend 2000 from 1.80 Mt at yearend 1999. Unwrought aluminum is defined by the IAI as aluminum in its basic cast form made from primary metal or from scrap and which is unworked in the metallurgical sense. IAI total aluminum inventories decreased to 3.09 Mt at yearend 2000 from 3.18 Mt at yearend 1999. Total aluminum is unwrought aluminum plus unprocessed scrap, metal in process, and finished semifabricated (mill) products (International Aluminium Institute, 2001).

Inventories of primary aluminum metal held by the LME decreased dramatically from 774,000 t at yearend 1999 to 322,000 t at yearend 2000. Aluminum alloy inventories, however, increased to 88,000 t at yearend 2000 from 78,000 t at yearend 1999 (London Metal Exchange Ltd., 2000).

Armenia.—The Government of Armenia and Russia's Sibirsky Aluminy signed a joint-venture agreement to rebuild the Armenal foil mill in Yerevan. Sibirsky agreed to invest about $32 million in exchange for 44% of the plant ownership. The remaining 56% would remain with the state-controlled Kanaker Aluminum Works. The mill, which had been idled for 6 years, was expected to reach its full capacity of about 2,200 t/mo of foil by the middle of 2001. Sibirsky planned to increase its ownership to 74% over 3 or 4 years (Interfax Mining & Metals Report, 2000a).

Australia.—Capral Aluminium Ltd. sold its 150,000 t/yr Kurri Kurri primary aluminum smelter in New South Wales to Germany's VAW Aluminium AG (Platt's Metals Week, 2000g). VAW, whose worldwide smelter capacity increased by 30% to 575,000 t/yr with this purchase, announced plans to modernize and expand capacity at Kurri Kurri by 15,000 t/yr before 2003 (Metal Bulletin, 2000w). Capral also announced plans to phase out its sheet rolling operations at Granville by the end of 2000. The associated metal recycling and remelt facility would be retained and converted to extrusion billet production. Capral intended to concentrate on its downstream processing and distribution business (Metal Bulletin, 2000g).

Rio Tinto plc became the sole owner of Comalco Ltd., a major Australian supplier of bauxite, alumina, and primary aluminum metal to the world market. Rio Tinto acquired the publicly held 27.6% of Comalco during the first half of 2000. Comalco's interests include the Weipa bauxite mine (100%) in Queensland, the Boké Mine (4%) in Guinea, the Gladstone alumina refinery (30%) in Queensland, the Eurallumina refinery (56%) in Italy, the Bell Bay (100%) and Boyne Island (54%) smelters in Australia, and the Tiwai Point smelter (79%) in New Zealand (Rio Tinto plc, 2001, p. 39).

Pechiney agreed to purchase AMP Life Limited's 15.5% direct stake in the Tomago primary aluminum smelter in New South Wales. The purchase would increase Pechiney's interest in the 440,000 t/yr smelter to 51.55% from 36.05%. The other participants in the Tomago joint venture are Gove Aluminium Finance Ltd. (36.05%) and VAW Tomago Inc. and VAW Australia Pty Ltd. with a combined stake of 12.4% (Pechiney, 2000a).

Alcoa of Australia Limited, a joint venture of Alcoa Inc. and WMC Ltd., announced the restart of its idled capacity at the Portland and Point Henry primary aluminum smelters. The capacity had been idled since the mid-1990s. Alcoa of Australia was operator and part owner of the 450,000-t/yr Portland smelter and 100% owner/operator of the 180,000-t/yr Point Henry smelter (American Metal Market, 2000b). On September 15, Alcoa increased its ownership in the Portland smelter to 55% from 45% with the purchase of Eastern Aluminium Ltd. (Alcoa, 2001b, p. 10-11).

Azerbaijan.—Fondel Metal Participants, a Dutch company, won a tender for the management of Azerbaijan's aluminum holding company, Azeraluminy. Fondel agreed to modernize the company's facilities that include the 60,000-t/yr Sumgait smelter, the Gyandja alumina refinery, and local alunite mines. The Gyandja refinery, which can process both imported bauxites and local alunite ore, was the company's only operational facility in 2000 (Metal Bulletin, 2000d).

Bahrain.—The Government of Bahrain approved in principle a $1.7 billion expansion project for Aluminium Bahrain B.S.C. (Alba) and passed the proposal on to the ministerial committee of finance and economy for further study. The project, if approved, would increase capacity at Alba's 500,000-t/yr primary aluminum smelter to 750,000 t/yr (American Metal Market, 2000a).

Brazil.—Vale do Rio Doce Alumínio S.A. (Aluvale) reported the start of a 43,000-t/yr expansion at its Alumínio Brasileiro S.A. (Albrás) primary aluminum smelter. The $90 million expansion at the 361,000-t/yr smelter was expected to be completed by September 2001 (Metal Bulletin, 2000a).

Cia Brasileira de Alumínio (CBA) began construction on a 70,000-t/yr expansion at its 237,000-t/yr primary aluminum smelter in Sao Paulo. The $400 million project, which also included investments in CBA's hydroelectric plants, was expected to be completed by the end of 2002 (Kinch, 2000).

Billiton plc acquired an indirect 2.1% stake in Companhia Vale do Rio Doce (CVRD) through its purchase of a 66.97% share of Sweet River Investment Ltd. The Sweet River assets correspond to a 7.74% share of Valepar SA, the controlling shareholder of CVRD. CVRD through its fully owned subsidiary Aluvale, has interests in the Albras and Santa Cruz primary aluminum smelters (Billiton plc, 2000a).

Canada.—On October 21, approximately 32 months after groundbreaking ceremonies, the first reduction cell at Alcan Aluminium Ltd.'s Alma smelter was energized. Startup of the smelter's 432 reduction cells will continue through the fall of

Digitized by Google

2001, at which time the smelter was expected to reach its full capacity of 400,000 t/yr (Alcan Aluminium Ltd., 2000i).

On December 8, Alcan announced that it would temporarily close 50,000 t/yr of capacity at its primary aluminum smelter in Kitimat, British Columbia, for at least 10 months. Alcan believed that the temporary shut down and other energy reduction steps would conserve enough energy to keep the other six potlines at the 272,000-t/yr smelter operational. An acute shortage of water in the Nechako Reservoir, the result of 3 consecutive years of low inflows into the reservoir, reduced the hydroelectric power availability and forced the company to take this action (Alcan Aluminium Ltd., 2000j).

Workers at the 372,000-t/yr Aluminerie de Bécancour primary smelter in Quebec accepted a new 4-year labor agreement that reportedly included a 3% wage increase the first year and 2.8% increases each year thereafter. The previous 6-year contract expired on June 30 (Platt's Metals Week, 2000a).

Lavalum, a joint venture of scrap processor SNF/Quebec Metal Recycle Inc. and the provincial Government of Quebec, announced the opening a new secondary aluminum smelter. The smelter was expected to produce 2,950 t/mo (6.5 million pounds per month) of aluminum alloys (Worden, 2000b).

China.—During the year, numerous expansion plans for primary aluminum smelters throughout China were announced.

Baotou Aluminium Group planned to add a new 50,000-t/yr potline to its 110,000-t/yr smelter by the end of 2001 (Platt's Metals Week, 2000e).

The 20,000-t/yr Hubei Aluminium Smelter received Government approval to proceed with a planned 100,000-t/yr expansion program (CRU Aluminium Monitor, 2000a).

Work reportedly began on the 100,000-t/yr expansion at the 85,000-t/yr Lanzhou Aluminium Smelter. Completion of the project was expected in 2 to 3 years (American Metal Market, 2000e).

The Taiiyuan Aluminium Works in Shanxi Province began construction work on a planned 80,000-t/yr expansion at its 30,000-t/yr primary aluminum smelter. Once the new line became operational at the end of 2001, the company planned to close one of the two existing 15,000-t/yr potlines because of pollution factors (Platt's Metals Week, 2000q).

Tongchuan Aluminium Industry commissioned a new 5,000-t/yr potline at its 50,000-t/yr smelter in Shaanxi Province (CRU Aluminium Monitor, 2000b).

Xiezhou Aluminium Plant in Shanxi Province reported the completion of a new 40,000-t/yr potline at its 30,000-t/yr smelter. The company planned to upgrade the existing potlines and increase capacity to 100,000 t/yr by the end of 2001 (Platt's Metals Week, 2000t).

Yunnan Aluminium Plant reportedly completed its smelter expansion increasing capacity from the previous 40,000 t/yr to 130,000 t/yr. The company was awaiting Government approval to further expand the smelter's capacity to 250,000 t/yr (Platt's Metals Week, 2000u).

Zunyi Aluminium Plant started construction on a new 100,000-t/yr potline at its 32,000-t/yr smelter in Guizhou Province, which could be completed in 2002 (Platt's Metals Week, 2000v).

Egypt.—The Aluminium Company of Egypt (Egyptalum) announced plans to increase capacity at its 195,000-t/yr primary smelter to 245,000 t/yr by 2002. In October 1997, a 50,000-t/yr prebaked potline was commissioned and an existing potline (Potline 5) was shut down. Egyptalum expects to complete the conversion of Potline 5 to prebake technology by mid-2002, thereby increasing the smelter's capacity to 245,000 t/yr (Aluminium Company of Egypt, Smelter, accessed May 25, 2001, at URL http://www.egyptalum.com.eg/smelter.html).

France.—PSA Peugot Citroën and Pechiney signed a strategic partnership agreement for the development of aluminum applications in Peuleot and Citroën vehicles. The 10-year agreement provides the framework for cooperation between the two groups with the aim of increasing production of mass-produced aluminum parts and making innovative developments for vehicle weight reduction (Pechiney, 2000b).

Germany.—VAW Aluminium AG and Sweden's Sapa AB, formerly Gränges AB, terminated their agreement aimed at VAW taking over Sapa's foil business, Eurofoil. VAW reported that it had withdrawn its application with the German cartel office after it became apparent that the office would not give its approval. The former agreement had included foil mills in Belgium, Luxembourg, and Sweden (Köhl, 2000).

Hungary.—Magyar Aluminium Rt (MAL) integrated its affiliates into one holding company to reduce administrative overhead and to simplify strategic planning. MAL incorporated Ajkai Timfold, owner of the 300,000-t/yr Ajka alumina refinery, and Inotai Aluminium, which owns 93% of the 35,000-t/yr Inota aluminum smelter (Metal Bulletin, 2000m).

India.—Alcan announced the sale of its 54.62% interest in Indian Aluminium Co., Ltd. (Indal) to Hindalco Industries Ltd. The purchase included about 100,000 t/yr of primary aluminum smelter capacity (Metal Bulletin, 2000b).

Hindalco's board of directors approved a $575 million expansion of its operations in Renukoot. Aluminum smelter capacity would be expanded to 342,000 t/yr from 242,000 t/yr and the alumina refinery capacity would increase to 660,000 t/yr from 450,000 t/yr. The expansion was expected to be completed by July 2002 (Raghuvanshi, 2000).

Expansion plans continued at National Aluminium Co. Ltd. Bauxite production capacity at the Panchpatmali Mine was scheduled to double to 4.8 Mt/yr by 2001. Capacity at the 800,000-t/yr alumina refinery at Damanjodi was expected to increase to 1.575 Mt/yr in early 2002, and the Angul smelter expansion that would increase capacity to 345,000 t/yr from 230,000 t/yr was expected to be commissioned by mid-2002 (Hall, 2000).

Indonesia.—Production at P.T. Indonesia Asahan Aluminium Co.'s (PT Inalum) primary aluminum smelter returned to 85% to 90% of its 225,000-t/yr capacity with 440 of its 510 pots on-line. Receding water levels in Lake Toba in 1998-99 had reduced hydroelectric power generation forcing PT Inalum to reduce production levels at the smelter by as much as 60% in mid-1998 (Platt's Metals Week, 2000c).

Iran.—The production rate at Almahdi Aluminium Corp.'s primary aluminum smelter at Bandar Abbas reached about 25,000 t/yr. The company expected the smelter, which was commissioned in June 1997, to reach full production of 110,000 t/yr by the end of 2001 (Metal Bulletin, 2000e).

Japan.—Alcoa announced that construction had begun on a new forged aluminum commercial vehicle wheel plant in Joetsu City, Niigata Prefecture, to meet increased demand for polished aluminum truck and bus wheels in Japan. The plant was expected to be operational by the latter half of 2001 and to reach full capacity in late 2002 (Alcoa Inc., 2000d).

Nippon Light Metal Co. Ltd. announced a major restructuring of its extrusion business that would close one-third of the

Digitized by Google

company's 33 extrusion lines by the end of March 2001. The company also reported the curtailment of production of aluminum substrates for computer disks (Metal Bulletin, 2000p).

Mitsubishi Materials Corp. and Mitsubishi Aluminium Co. Ltd. announced plans to build an integrated aluminum recycling plant that would consolidate aluminum UBC recycling operations that were being conducted at several different locations. The plant would convert UBCs into slabs ready for rolling into can stock. Slab production, which was expected to start in 2001, was estimated at 60,000 t/yr (Metal Bulletin, 2000o).

Korea, Republic of.—Alcan, through its subsidiary Alcan Taihan Aluminium Limited, acquired Aluminium of Korea Limited (Koralu). The acquisition of Koralu positioned Alcan as Asia's leading aluminum rolled products company. The Koralu facility included casting, hot rolling, cold rolling, and extensive finishing operations as well as aluminum foundry alloy and billet operations supported by a research and development center (Alcan Aluminium Ltd., 2000e).

Malaysia.—Malaysia's Aluminium Industries commissioned a new aluminum foil mill. The plant was capable of producing foil down to 0.006 millimeters thickness for the pharmaceutical and food packaging industries (Metal Bulletin, 2000n).

Mexico.—Hayes Lemmerz launched a capacity expansion program at its Chihuahua wheel plant that was expected to increase production to 1.2 million cast light-alloy wheels per year from 300,000 wheels per year (Wrigley, 2000e).

Mozambique.—On September 29, the Mozambique Aluminium Co.'s (Mozal) primary aluminum smelter near Maputo was officially opened. The feasibility study for the smelter started in November 1995, and construction began in May 1998. The 250,000-t/yr smelter uses Pechiney's AP30S technology and has one potline with a total of 288 pots. The smelter is a joint venture involving Billiton plc (47%), Mitsubishi Corp. (25%), the Industrial Development Corp. of South Africa Ltd. (24%), and the Government of Mozambique (4%). The smelter produced its first metal on June 18, 2000, and exported its first consignment of ingots to Europe in August (Billiton plc, 2000b; Millbank, 2000). By the end of December, all 288 pots were in operation (Mozambique Aluminium Co., 2000). Billiton reported that the company will complete feasibility studies into the possible construction of a second 250,000-t/yr potline at Mozal. Any decision, however, could be at least a year away (Metal Bulletin, 2000l).

Nigeria.—Reynolds, which was merged with Alcoa, transferred its 10% interest in Aluminium Co. of Nigeria (Alscon) to the other private partner in the company, Germany's Ferrostaal AG, whose ownership increased to 30%. The remaining 70% of Alscon was owned by the Nigerian government. The responsibility for the technical running of the 193,000-t/yr smelter, which has been closed since June 1999, was also transferred from Reynolds to Ferrostaal (Metal Bulletin, 2000r).

Norway.—Elkem ASA's aluminum operations are organized in Elkem Aluminium ANS, a 50-50 partnership with Alcoa. In 2000, Alcoa acquired over 30% of the outstanding shares of Elkem ASA (Alcoa Inc., 2001b, p. 10).

Elkem Aluminium ANS announced plans to modernize and expand its 121,000-t/yr Mosjøen primary aluminum smelter. Two of the plants four potrooms (two potlines) were converted from Soderberg to prebaked technology in 1989. The remaining Soderberg line is scheduled to be converted and expanded by 2003. Upon completion, annual capacity at the smelter would increase to 188,000 t/yr (Elkem ASA, 2000).

Meanwhile, conversion work on Potrooms 1 and 2 at the 83,000-t/yr Lista smelter was expected to be completed in the first half of 2001. The installation of a new Soderberg technology was expected to yield significant environmental improvements while increasing production capacity by 10,000 t/yr (Elkem ASA, 2001, p. 26).

Norsk Hydro ASA confirmed that the company will invest approximately $600 million in the expansion and modernization of its Sunndal primary aluminum smelter. A new smelter with a production capacity of 238,800 t/yr will be built on the site and a 66,000-t/yr Soderberg facility, which was started in 1954, will be closed gradually to prevent the loss of production during construction. The company stated that the remaining 90,000 t/yr of existing capacity will continue to operate. The new smelter will consist of 340 new cells using Hydro's HAL250 technology. Upon completion in 2004, total capacity at the site will increase to 328,800 t/yr, making it the largest aluminum smelter in Europe (outside of Russia). The design of the cell linings and rectifiers will be such that amperage can gradually be increased, providing an additional 22,000 t/yr of production capacity by 2007 (Norsk Hydro ASA, 2000a: Norsk Hydro ASA, 2001b).

Oman.—A feasibility study for a proposed $2.5 billion, 480,000-t/yr primary aluminum smelter in Sohar was completed. An implementation review to identify potential technologies and project funding was begun (Mining Journal, 2000b).

Russia.— A new aluminum company, Russky Aluminy (Russian Aluminium), was formed by combining the assets of the Sibneft shareholder group and Siberian Aluminium. Russian Aluminium manages about 70% of Russia's primary aluminum smelting capacity. The company controls Russia's three largest smelters—Bratsk (900,000 t/yr), Krasnoyarsk (800,000 t/yr), and Sayansk (400,000 t/yr). On the alumina side, the company controls the Achinsk (900,000 t/yr) and the Nikolayev (1.05 Mt/yr) refineries. The downstream operations that are either fully or partly owned by the company include the Samara Metallurgical Plant, the Sayanal foil mill, the Rostar can plant, and the Belaya Kalitva Metallurgical Production Assn. (Metal Bulletin, 2000s).

A second new group, SUAL Holding, was a merger of the aluminum assets of Siberian-Urals Aluminium Co. and the Trustconsult Group. SUAL controls the Irkutsk (262,000 t/yr), Bogoslovsk (162,000 t/yr), Uralsky (70,000 t/yr), and Kandalaksa (63,000 t/yr) primary aluminum smelters. The company also owns the Bogoslovsk (930,000 t/yr) and Uralsky (570,000 t/yr) refineries, the Northern and Southern Urals bauxite mines plus the Srende-Timan bauxite deposits (CRU Alumina Monitor, 2000). Downstream facilities include the Kamensk-Uralsky Metallurgy Plant (rolling mill), the Mikhailovsky Nonferrous Metal Processing Plant (Mikhalum foil plant), and the Irkutsk and Kirinsky cable plants (Interfax Mining & Metal Report, 2000d).

Scotland.—Alcan reported the closure of its 8,000-t/yr primary aluminum smelter in Kinlochleven. The Kinlochleven smelter, built in 1907, was one of the world's oldest smelters still in operation (Alcan Aluminium Ltd., 2000f).

South Africa.—Billiton was conducting a feasibility study for an additional 125,000-t/yr potline at its 500,000-t/yr Hillside

Digitized by Google

smelter (Mining Journal, 2000a).

Spain.—Alcoa Inespal built a new aluminum extrusion plant at La Salva del Camp to make extruded aluminum profiles for the automotive and construction industries. By yearend, a 1,350-t press with an output of 4,000 t/yr was operational. A second line was expected to startup in August 2001, doubling the plant's capacity (Alcoa Inc., 2001a, p. 24).

Norsk Hydro announced plans to build a 60,000-t/yr aluminum remelt plant in Azuqueca near Madrid. The plant, which will produce extrusion ingot from scrap for growing markets in Spain and Portugal, was expected to be completed by yearend 2001 (Norsk Hydro ASA, 2000e).

Sweden.—Gränges AB changed its name to Sapa AB. Sapa was already being used as a corporate and brand name by Gränges' aluminum extrusion division. The formal change of name and company logo took place in mid-February (Metal Bulletin, 2000k).

Glencore International AG reported that it had acquired Kubikenborg Aluminium Sundsvall AB (KAS), owner of the 100,000-t/yr primary aluminum smelter in Sundsvall, Sweden. KAS had been formed by the plant's management group that bought the smelter from Gränges in 1998 (American Metal Market, 2000d).

Switzerland.—Algroup, the aluminum division of Alusuisse Lonza Group Inc., announced its decision to continue the operation of its 35,000-t/yr primary aluminum smelter at Steg at least until the end of 2005. The continuation of the Steg plant, which was originally scheduled for closure at the end of 2001, became possible because of the extension of a fixed power price and supply contract to 2005. The continuation of plant operations will require some technical adjustments that will result in an increase in capacity to 43,000 t/yr (algroup, 2000).

Norsk Hydro signed an agreement with Aluminium Martigny S.A. to continue operating its remelt plant in Martigny. The agreement saved the plant, which produced about 25,000 t/yr of extrusion billet and foundry alloys, from imminent closure. While the potrooms at the Martigny primary smelter will remain closed, Norsk Hydro will operate the casthouse to produce specialty products for extruders and foundries in Europe (Norsk Hydro ASA, 2000d).

Taiwan.—New Sun Metal Industry Co. completed the expansion of its secondary aluminum smelter that increased capacity to 156,000 t/yr. The expansion enabled the company to diversify into sheet rolling, t-bar, anode, and deox production (Metal Bulletin, 2000u).

United Kingdom.—Alcan reported the restart of 50,000 t/yr of primary aluminum capacity at its smelter in Lynemouth to compensate for the closure of Alcan's Isle Maligne smelter in Canada and the Kinlochleven smelter in Scotland. The restart was completed by the end of the year (Alcan Aluminium Ltd., 2000f).

Alcan also announced the planned closure of its foil plant in Rogerstone, Newport, South Wales by June 2001. Some products will be transferred to other plants in the Alcan network but the majority of the plant's business will be discontinued. The larger Rogerstone sheet facility on the same site will continue to operate and remain a key part of Alcan's sheet manufacturing system in Europe (Alcan Aluminium Ltd., 2000d).

Alcoa announced the acquisition of British Aluminium. The acquisition included three soft-alloy extrusion operations at Banbury, St. Helens, and Latchford, England; a heat-treat plate mill in Kitts Green, Birmingham, England; and a sheet mill in Dolgarrog, Wales. The acquisition also included two distribution businesses, Baco Metal Centres and Aluminium Supply Aerospace, with branches located throughout the United Kingdom and Ireland (Alcoa Inc., 2000l).

Alcoa also acquired Baco Consumer Products, Ltd., headquartered near London. Baco is the United Kingdom's leading supplier of household wraps, including aluminium foil, plastic bags, cling film, and trash bags (Alcoa Inc., 2000c).

Alcoa announced the acquisition of MCG Closures Limited from Wassall plc. The acquisition included plants near Birmingham, England; Rieti, Italy; and a distribution center in the Netherlands. MCG became part of Alcoa Closure Systems International, 1 of 25 Alcoa business units and a leading global manufacturer of plastic closures for the beverage industry (Alcoa Inc., 2000a).

Norsk Hydro signed an agreement with Aluminium Holding UK Ltd. to purchase its entire shareholding in Deeside Aluminium Ltd. in Wrexham, Wales. Deeside operates an extrusion ingot casting plant that uses aluminum scrap as a feed source. The plant has an output of 38,000 t/yr of extrusion ingot. Upon approval of the takeover by the United Kingdom authorities, Norsk Hydro plans a significant improvement program that will improve productivity and increase capacity to 43,000 t/yr. The improvement program will also pave the way for a possible future expansion to 60,000 t/yr (Norsk Hydro ASA, 2000c).

Ukraine.—Kaiser completed a technical feasibility study for the reconstruction of smelting capacity at Zaporozhye Aluminum Works (Zalk). The conversion of the smelter's Soderberg technology to prebaked anode technology was expected to increase capacity at the 110,000-t/yr primary aluminum smelter to about 160,000 t/yr and to reduce costs. Financing for this conversion was expected to be secured from the sale of 68.1% of the state-owned shares in the company. The Government would retain 25% of the shares and employees 6.9% (Interfax Mining & Metals Report, 2000c). At the end of November, the Ukranian State Property Fund announced that Kremenchug Auto Works (Kraz) Foreign Trade Company had won the tender for the shares in Zalk with a bid of $101.5 million. Glencore International reportedly owns about 90% of the shares in Kraz Foreign Trade Company (Interfax Mining & Metals Report, 2000b).

Ukrainian Aluminium Co., a company linked with Russia's Sibirsky Aluminy, purchased a 30% stake in the 1.05 Mt/yr Nikolayev alumina plant. Ukrainian Aluminium planned to modernize the alumina plant and increase its capacity to 1.3 Mt/yr. As a condition of the sale, the company also agreed to build a primary aluminum smelter in the Ukraine (Platt's Metals Week, 2000n). Construction of the new 100,000-t/yr smelter was due to begin by 2002 and would take 5 to 6 years to complete (Platt's Metals Week, 2000s). By the end of 2000, Ukrainian Aluminium acquired an additional 15% stake in the Nikolayev alumina refinery (Platt's Metals Week, 2000r).

Venezuela.—Norsk Hydro acquired a 33.3% stake in Pianmeca, located in Puerto Ordaz next to the Venalum smelter, which will supply liquid aluminum to the casthouse. Pianmeca expected to produce 30,000 t of extrusion ingots and 8,000 t of wire rod in 2001. Norsk Hydro planned to increase future production levels at the plant through investments and plant improvements (Norsk Hydro ASA, 2000f).

Technology

Toronto University scientists completed an evaluation of Aluminum Power Inc.'s aluminum-air fuel cell. The scientists reported that "although nickel-metal-hydride and lithium-ion battery systems represent a tremendous advance in battery technology, their power pales in comparison with the energy available from an aluminum-air cell." The cell generates power through an electro mechanical reaction between the aluminum, placed in an alkaline solution, and oxygen from the air. Electricity is produced as the aluminum oxidizes in the alkaline solution. Key to the cell's effectiveness is its high energy output, which results from the characteristic energy density of aluminum and the fact that three electrons are released for every atom of aluminum reacted (American Metal Market, 2000g).

The aluminum-air cell technology can be adapted to a variety of applications, including electric vehicles, emergency power sources, and portable electronic devices. Aluminum Power announced that it had achieved 8 hours of talk time and 5½ days of standby power using its newly developed aluminum-air fuel cell for mobile telephones in a digital mode compared with 2 hours of talk time for lithium-ion or nickel-cadmium batteries. The company claimed that when the technology is perfected about 25 hours of talk time and 240 hours of standby power would be possible (Pinkham, 2000).

Outlook

Weakness in the national economies of most areas of the world is expected to lead to very little growth, or possibly a small decrease, in demand for aluminum in 2001. It is anticipated that this weakness will be short-lived and that demand will pick up in 2002 and thereafter.

On the supply side, energy costs and shortages continued to force companies to temporarily idle smelter capacity. By July 2001, the United States had idled almost 1.8 Mt of capacity; combined with announced capacity reductions in Brazil and Canada, almost 2.2 Mt/yr of production capacity was removed from the world supply. However, the reduction in demand and additional production, from new smelters in Canada and Mozambique plus brownfield expansions that are coming on-stream, are expected to keep world supply and demand fairly balanced in 2001. In later years, however, if demand picks up and the energy cost and supply situations have not been reversed, shortages could appear.

On the demand side, the automotive and construction industries are expected to be the drivers for aluminum demand in the future. Growth in the packaging and container industry has stabilized, especially in the United States and Europe. There is still room for growth in the packaging industries of Asia and Latin America, but even there the growth rate over the past few years has slowed. Overall, world demand is expected to continue to grow, despite a possible drop in the growth rate for the next year or so as the world economies begin their recoveries.

TABLE 1
SALIENT ALUMINUM STATISTICS 1/

(Thousand metric tons, unless otherwise specified)

	1996	1997	1998	1999	2000
United States:					
Primary production	3,577	3,603	3,713	3,779	3,668
Value (million dollars)	$5,630	$6,120	$5,360	$5,470	$6,030
Price (average cents per pound), U.S. market (spot)	71.3	77.1	65.5	65.7	74.6
Inventories (December 31):					
Aluminum industry 2/	1,860	1,860	1,930	1,870	1,550
LME stocks in U.S. warehouses 3/	33	8	13	14	(4/)
National Defense Stockpile	57	(4/)	--	--	--
Secondary recovery: 5/	3,310	3,550	3,440	3,690 r/	3,450
New scrap	1,730	2,020	1,950	2,120 r/	2,080
Old scrap	1,570	1,530	1,500	1,570 r/	1,370
Exports (crude and semicrude)	1,500	1,570	1,590	1,640	1,760
Imports for consumption (crude and semicrude)	2,810	3,080	3,550	4,000	3,910
Aluminum industry shipments 6/	8,330	8,880	9,260	9,840	9,840
Supply, apparent 7/	8,340	8,740	9,040	9,890 r/	9,610
Consumption, apparent 8/	6,610	6,720	7,090	7,770 r/	7,530
World production	20,800 r/	21,700 r/	22,600 r/	23,600 r/	24,000 e/

e/ Estimated. r/ Revised. -- Zero.
1/ Data are rounded to no more than three significant digits, except "Primary production" and "Prices."
2/ Includes ingot, semifabricated material, and scrap. Data for 1996 through 1998 from Current Industrial Reports, Series M33-D, U.S. Department of Commerce, U.S. Census Bureau. Data for 1999 and 2000 from Aluminum Association Inc.
3/ Includes aluminum alloyed material.
4/ Less than 1/2 unit.
5/ Metallic recovery from purchased, tolled, or imported new and old scrap expanded for full industry coverage.
6/ Shipped to domestic industry.
7/ Defined as domestic primary metal production plus secondary recovery plus imports minus exports plus adjustments for Government and industry stocks changes.
8/ Apparent supply less recovery from purchased new scrap.

TABLE 2
PRIMARY ANNUAL ALUMINUM PRODUCTION CAPACITY IN THE UNITED STATES, BY COMPANY 1/

Company	Yearend capacity (thousand metric tons) 1999	2000	2000 ownership
Alcan Aluminum Corp.:			
Sebree, KY	186	186	Alcan Aluminium Ltd., 100%.
Alcoa Inc.: 2/			
Alcoa, TN	210	210	Alcoa Inc., 100%.
Badin, NC	115	115	Do.
Evansville, IN (Warrick)	300	300	Do.
Ferndale, WA (Intalco)	272	272	Alcoa Inc., 61%; Mitsui and Co. Ltd., 32%; YKK Corp., 7%
Frederick, MD (Eastalco)	174	174	Do.
Longview, WA 3/	204	204	Alcoa Inc., 100%
Massena, NY 3/	123	123	Do.
Massena, NY	125	125	Do.
Mount Holly, SC	215 r/	215	Alcoa Inc., 50.3%; Century Aluminum Co., 49.7%.
Rockdale, TX	315	315	Alcoa Inc., 100%.
Troutdale, OR 3/	121	121	Do.
Wenatchee, WA	220	220	Do.
Total	2,390 r/	2,390	
Century Aluminum Co.:			
Ravenswood, WV	168 r/	168	Century Aluminum Co., 100%.
Columbia Falls Aluminum Co.:			
Columbia Falls, MT	168	168	Glencore AG, 100%
Goldendale Aluminum Co.:			
Goldendale, WA	168	168	Private interest, 60%; employees, 40%.
Kaiser Aluminum & Chemical Corp.:			
Mead, WA (Spokane)	200	200	MAXXAM Inc., 100%.
Tacoma, WA	73	73	Do.
Total	273	273	
NSA:			
Hawesville, KY	237	237	Southwire Co., 100%.
Noranda Aluminum Inc.:			
New Madrid, MO	222 r/	222	Noranda Mines Ltd., 100%.
Northwest Aluminum Corp.:			
The Dalles, OR	82	82	Private interests, 100%.
Ormet Primary Aluminum Corp.:			
Hannibal, OH	255	257	Ormet Corp., 100%.
Vanalco Inc.:			
Vancouver, WA	116	116	Vanalco Inc., 100%.
Grand total	4,270	4,270	

r/ Revised.
1/ Data are rounded to no more three significant digits; may not add to totals shown.
2/ Individual plant capacities are U.S. Geological Survey estimates based on company reported total.
3/ Alcoa and Reynolds merged in June 2000.

TABLE 3
U.S. CONSUMPTION OF AND RECOVERY FROM PURCHASED NEW AND OLD ALUMINUM SCRAP, BY CLASS 1/ 2/

(Metric tons)

Class	Consumption	Calculated recovery: Aluminum	Calculated recovery: Metallic
1999:			
Secondary smelters	2,130,000 r/	1,450,000 r/	1,560,000 r/
Integrated aluminum companies	1,230,000	1,010,000	1,080,000
Independent mill fabricators	787,000	674,000	720,000
Foundries	101,000	85,300	91,300
Other consumers	8,880	8,810	8,810
Total	4,250,000 r/	3,230,000 r/	3,460,000 r/
Estimated full industry coverage	4,560,000 r/	3,450,000 r/	3,690,000 r/

See footnotes at end of table.

TABLE 3–Continued
U.S. CONSUMPTION OF AND RECOVERY FROM PURCHASED NEW AND OLD ALUMINUM SCRAP, BY CLASS 1/ 2/

(Metric tons)

Class	Consumption	Calculated recovery	
		Aluminum	Metallic
2000:			
Secondary smelters	1,960,000	1,350,000	1,450,000
Integrated aluminum companies	1,060,000	873,000	930,000
Independent mill fabricators	800,000	689,000	736,000
Foundries	95,600	80,200	85,800
Other consumers	14,600	14,600	14,600
Total	3,940,000	3,010,000	3,220,000
Estimated full industry coverage	4,220,000	3,220,000	3,450,000

r/ Revised.
1/ Excludes recovery from other than aluminum-base scrap.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.

TABLE 4
U.S. STOCKS, RECEIPTS, AND CONSUMPTION OF PURCHASED NEW AND OLD ALUMINUM SCRAP AND SWEATED PIG IN 2000 1/ 2/

(Metric tons)

Class of consumer and type of scrap	Stocks, January 1	Net receipts 3/	Consumption	Stocks, December 31
Secondary smelters:				
New scrap:				
Solids	12,800 r/	300,000	294,000	18,300
Borings and turnings	7,950 r/	325,000	324,000	9,660
Dross and skimmings	4,260 r/	531,000	532,000	4,080
Other 4/	3,750 r/	222,000	222,000	3,060
Total	28,700 r/	1,380,000	1,370,000	35,100
Old scrap:				
Castings, sheet, clippings	6,650 r/	352,000	354,000	4,730
Aluminum-copper radiators	2,130 r/	20,600	21,000	1,710
Aluminum cans 5/	1,170 r/	88,200	88,000	1,350
Other 6/	5,930 r/	119,000	119,000	5,990
Total	15,900 r/	580,000	582,000	13,800
Sweated pig	465 r/	10,800	11,100	191
Total secondary smelters	45,100 r/	1,970,000	1,960,000	49,100
Integrated aluminum companies, foundries, independent mill fabricators, other consumers:				
New scrap:				
Solids	22,400	801,000	806,000	17,900
Borings and turnings	104	23,100	22,900	318
Dross and skimmings	131	8,480	8,470	137
Other 4/	9,690 r/	212,000	214,000	6,930
Total	32,400 r/	1,040,000	1,050,000	25,300
Old scrap:				
Castings, sheet, clippings	3,060	148,000	144,000	6,940
Aluminum-copper radiators	439	6,500	6,700	241
Aluminum cans	13,600 r/	750,000	737,000	26,900
Other 6/	22	29,800	29,800	22
Total	17,100 r/	935,000	918,000	34,100
Sweated pig	86	2,840	2,740	179
Total integrated aluminum companies, etc.	49,500 r/	1,980,000	1,970,000	59,600
All scrap consumed:				
New scrap:				
Solids	35,200 r/	1,100,000	1,100,000	36,200
Borings and turnings	8,050 r/	348,000	347,000	9,970
Dross and skimmings	4,400 r/	540,000	540,000	4,210
Other 4/	13,400 r/	433,000	437,000	9,990
Total	61,100 r/	2,420,000	2,420,000	60,400

TABLE 4--Continued
U.S. STOCKS, RECEIPTS, AND CONSUMPTION OF PURCHASED NEW AND OLD ALUMINUM SCRAP AND SWEATED PIG IN 2000 1/ 2/

(Metric tons)

Class of consumer and type of scrap	Stocks, January 1	Net receipts 3/	Consumption	Stocks, December 31
All scrap consumed--Continued:				
Old scrap:				
Castings, sheet, clippings	9,710 r/	500,000	498,000	11,700
Aluminum-copper radiators	2,570 r/	27,100	27,700	1,960
Aluminum cans	14,700 r/	838,000	825,000	28,300
Other 6/	5,960 r/	149,000	149,000	6,010
Total	33,000 r/	1,510,000	1,500,000	47,900
Sweated pig	551 r/	13,600	13,800	370
Total of all scrap consumed	94,600 r/	3,950,000	3,940,000	109,000

r/ Revised.
1/ Includes imported scrap. According to reporting companies, 24.5% of total receipts of aluminum-base scrap, or 974,000 metric tons, was received on toll arrangements.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.
3/ Includes inventory adjustment.
4/ Includes data on foil, can stock clippings, and other miscellaneous.
5/ Used beverage cans toll treated for primary producers are included in secondary smelter tabulation.
6/ Includes municipal wastes (includes litter) and fragmentized scrap (auto shredder).

TABLE 5
PRODUCTION AND SHIPMENTS OF SECONDARY ALUMINUM ALLOYS BY INDEPENDENT SMELTERS IN THE UNITED STATES 1/

(Metric tons)

	1999		2000	
	Production	Net shipments 2/	Production	Net shipments 2/
Diecast alloys:				
13% Si, 360, etc. (0.6% Cu, maximum)	24,700 r/	24,600 r/	30,600	30,200
380 and variations	424,000 r/	419,000 r/	515,000	526,000
Sand and permanent mold:				
95/5 Al-Si, 356, etc. (0.6% Cu, maximum)	31,300 r/	31,200 r/	127,000	126,000
No. 319 and variations	148,000 r/	139,000 r/	137,000	139,000
F-132 alloy and variations	38,100 r/	37,500 r/	30,400	30,200
Al-Mg alloys	639	639	639	639
Al-Zn alloys	2,520 r/	1,950 r/	2,240	2,930
Al-Si alloys (0.6% to 2.0% Cu)	2,020	2,020	2,020	2,020
Al-Cu alloys (1.5% Si, maximum)	924	924	2,290	2,290
Al-Si-Cu-Ni alloys	949	952	949	951
Other	712	761	1,320	1,350
Wrought alloys, extrusion billets	221,000 r/	221,000 r/	210,000	210,000
Miscellaneous:				
Steel deoxidation	(3/)	(3/)	(3/)	(3/)
Pure (97.0% Al)	(3/)	(3/)	(3/)	(3/)
Aluminum-base hardeners	3,470	3,480	3,470	3,470
Other 4/	125,000 r/	121,000 r/	122,000	124,000
Total	1,020,000 r/	1,000,000 r/	1,190,000	1,200,000
Less consumption of materials other than scrap:				
Primary aluminum	77,400 r/	XX	77,600	XX
Primary silicon	49,200 r/	XX	50,200	XX
Other	10,400 r/	XX	16,700	XX
Net metallic recovery from aluminum scrap and sweated pig consumed in production of secondary aluminum ingot 5/	887,000 r/	XX	1,040,000	XX

r/ Revised. XX Not applicable.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes inventory adjustment.
3/ Withheld to avoid disclosing company proprietary data; included with "Miscellaneous: Other."
4/ Includes other die-cast alloys.
5/ No allowance made for melt-loss of primary aluminum and alloying ingredients.

e/ Estimated. r/ Revised. -- Zero.

1/ World totals and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Primary aluminum is defined as "The weight of liquid aluminum as tapped from pots, excluding the weight of any alloying materials as well as that of any metal produced from either returned scrap or remelted materials." International reporting practices vary from country to country, some nations conforming to the foregoing definition and others using different definitions. For those countries for which a different definition is given specifically in the source publication, that definition is provided in this table by footnote. Table includes data available through May 11, 2001.

3/ Reported figure.

4/ Primary ingot plus secondary ingot.

5/ Ingot and rolling billet production.

6/ Primary ingot.

7/ Excludes high-purity aluminum containing 99.995% or more as follows, in metric tons: 1996--29,351; 1997--36,136; 1998--35,063; 1999--34,893 (revised); and 2000--40,956.

8/ Primary unalloyed ingot plus secondary unalloyed ingot.

9/ Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

ANTIMONY

By James F. Carlin, Jr.

Domestic survey data and tables were prepared by Evangeline J. Hemphill, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

About one-half of the primary antimony used in the United States went into flame-retardants; most of the remainder was used by the transportation, chemical, ceramics, and glass industries. Secondary antimony, which was derived almost entirely from recycled lead-acid batteries, was used in the manufacture of new batteries. The price of antimony metal, on average, was almost 5% higher than that of 1999. World production rose 9%.

A small amount of antimony was recovered as a byproduct of the mining of silver-copper ores at one mine in Idaho, but almost all primary antimony metal and oxide produced domestically originated from raw material imports. Primary smelter production declined 12%. Most domestic smelting consisted of upgrading imported antimony trioxide to a higher purity. Primary antimony metal and oxide, valued at $41 million, were produced by four companies operating four plants—two in Texas and one each in Montana and New Jersey. One of these primary smelters ceased production permanently during the year. Secondary antimony was recovered from scrapped lead-acid batteries at secondary lead smelters. The amount of antimony used by battery manufacturers is substantially lower than it was 10 years ago because of changing materials requirements for batteries. Industry stocks declined slightly (table 4).

Antimony was mined as a principal product and was a byproduct of the smelting of base-metal ores in 15 countries. Ninety-five percent of world primary antimony was mined in China (85%), South Africa (4%), Russia (4%), and Bolivia (2%) (table 9). World antimony reserves were estimated to be 2.1 million metric tons (Carlin, 2001).

Legislation and Government Programs

Sales of antimony from the National Defense Stockpile (NDS) proceeded for the eighth consecutive year. Sales were conducted on a negotiated bid basis and were held by Defense National Stockpile Center (DNSC) on the third Monday of each month. There was no maximum limit on the quantity for which a company could submit a bid, but the minimum quantity allowed was 18,144 kilograms (40,000 pounds). The materials offered were grade A and grade B ingots, cake, and broken pieces. All antimony sulfide ore held in the NDS has been sold. In calendar year 2000, 4,536 metric tons (t) of antimony was sold. At yearend 2000, the antimony inventory in the DNSC was 8,275 t. Antimony was stockpiled in Government warehouses at three depots, with Somerville, NJ, holding the largest amount (Defense Logistics Agency, 2000).

Production

Mine.—In the Coeur d'Alene District of Idaho, Sunshine Mining Co., the sole domestic antimony producer, recovered antimony-in-concentrate as a byproduct of the treatment of complex silver-copper-antimony sulfide ore. The company answered the U.S. Geological Survey (USGS) production survey for 2000; output data are not published, however, in order to protect company proprietary information.

Smelter.—The domestic producers of primary antimony metal and oxide products were Amspec Chemical Corp., Gloucester City, NJ; Anzon Inc., Laredo, TX; Laurel Industries Inc., La Porte, TX; and U.S. Antimony Corp., Thompson Falls,

Antimony in the 20th Century

In 1900, the amount of antimony obtained from domestic ores (about 200 metric tons) was just a small fraction of the amount consumed in the United States. A moderate amount (about 1,500 tons) of antimony ore was imported and smelted in the country. But even these sources together comprised only about one-half of the total amount of antimony consumed domestically. The balance came from crude antimony in various forms that was imported for smelting. Sources of the imported antimony materials are unknown. In 1900, alloying was the major domestic use of antimony. Perhaps foremost among antimony alloys was an alloy of the metal and lead, which was widely used in the manufacture of printing type metal. Antimony imparted hardness to the alloy and had the property of expanding at the moment of solidifying, thus giving to the type a clean, sharp face. Some antimony was used in the making of babbitt metal, an antifriction alloy used in moving parts for railroad locomotives. Early in the century, pewter contained 7% antimony. A small amount of antimony was used in medicines. Total antimony consumption in 1900 in the United States was about 3,000 tons.

In 2000, the amount of antimony obtained from domestic ores (about 400 tons) was only a minuscule fraction of the antimony used in the United States. Antimony ores and crude antimony imported and smelted in the United States satisfied the bulk of the country's needs. Idaho was the only State producing antimony-in-concentrate as a byproduct of treating complex silver-copper-antimony sulfide ore. Four domestic antimony smelters processed various forms of antimony mostly into antimony trioxide used primarily for flame-retardant chemicals. Flame-retardant chemicals were a new use for antimony starting in the early 1970s and experienced strong growth since that time under the impetus of fire safety concerns about clothing for infants, plastic toys, automobile and aircraft seat covers, etc. China, the world's leading antimony producer in 2000, was the major foreign source of antimony trioxide for the United States. Total antimony use in 2000 in the Nation was about 16,700 tons.

Digitized by Google

MT. The Anzon facility closed permanently near yearend. All replied to the USGS request for production data.

Secondary.—Old scrap, mostly lead battery plates, was the predominant source of the secondary antimony output. New scrap, mostly in the form of drosses and residues from various sources, supplied the remainder. Antimonial lead was the main market for scrap antimony.

Consumption

Reported consumption of primary antimony in 2000 was 24% above that in 1999. Flame-retardants, especially plastics, accounted for most of the increase. Lead-antimony alloys were used in automotive vehicle batteries, ammunition, corrosion-resistant pumps and pipes, tank linings, roofing sheet solder, cable sheaths, and antifriction bearings. Antimony trioxide, often dissolved in an organic solvent, was used to enhance the flame-retardant properties of plastics, rubber, textiles, and other combustibles. Antimony also was used as a decolorizing and refining agent in some forms of glass such as optical glass.

Of the 164 companies to which a USGS consumption survey was sent, 140 firms responded. Consumption data were estimated for the remaining 24 firms.

Prices

In 2000, antimony prices varied within a fairly narrow range, starting and ending the year at about the same level. The New York dealers' antimony metal price, published by Platt's Metals Week, started the year at $0.63 to $0.70 per pound and finished the year at $0.68 to $0.73 per pound. This price averaged $0.66 per pound for the year compared with $0.63 per pound in 1999. This small increase was the first after 3 years of relatively large decreases. The price range for high-tint antimony trioxide, published by American Metal Market, was $0.90 to $1.05 per pound at the start of the year and $0.89 to $1.25 per pound at the end of the year.

Trade

Imports of antimony were, as is usually the case, much larger than exports—about five-fold larger in 2000 (tables 5-8). Imports rose slightly, with the categories of ore/concentrate and oxide registering the only gains. Australia emerged as the largest supplier of antimony ore and concentrate, accounting for 38% of the total. China remained the dominant provider of antimony metal and antimony oxide, supplying 88% of the former, and 47% of the latter.

Exports of metal alloys, waste and scrap more than doubled. Exports of antimony oxide almost doubled.

World Review

Bolivia.—The privatization sale of Corporacíon Minera de Bolivia's shuttered Vinto antimony smelting plant was concluded with a $1.1 million offer from Colquiri SA, a subsidiary of Bolivia's biggest mining organization, Corporacíon Minera de Sur. Colquiri's bid was backed by the Commonwealth Development Corp. Ltd. (UK) and exceeded by 11 times the $100,000 base price set by Banque Parbas, the Government's advisor for the sale (Metal Bulletin, 2000a).

China.—Reports in 2000 indicated that China's Government intended to further limit the export of antimony products. The aim of this policy was to hold exports to 60,000 t in 2000 compared with the official quota of 80,000 t in each of the previous 2 years. The Ministry of Foreign Trade and Economic Cooperation indicated that no new export licences were to be granted until 2001.

Government officials believed that smuggling of antimony, which in previous years accounted for a significant tonnage of antimony shipped abroad, had been virtually eliminated due to greater efforts against illegal shipments. Officials also projected domestic Chinese antimony consumption at 10,000 t in 2000 (Metal Bulletin, 2000b).

The Huan Dong Metal Materials Plant in Guangxi announced plans to produce 10,000 t of antimony trioxide in 2000, up 25% from 1999 output. Guangxi accounts for about 80% of China's antimony output (Platt's Metals Week, 2000a).

The Guangxi Nandan Longquan Mining and Smelting Works completed an expansion that began a year earlier, doubling ore handling capacity from 2,400 metric tons per day (t/d) to 4,800 t/d. Longquan, which previously had the capacity to produce 6,000 metric tons per year (t/yr) of antimony ingot, reached a capacity of 15,000 t/yr. The cost of the expansion project was estimated at $12 million. Longquan accumulated 100,000 t of antimony concentrate for processing in its smelter. Its antimony ingot output in 1999 was 3,500 t; an output of 7,000 t was expected in 2000 (Platt's Metals Week, 2000b).

Outlook

Domestic antimony consumption, especially for important uses such as flame retardants, is likely to remain strong for the near future. A few new antimony mines have been developed in recent years (in Canada, for example) but continuing low antimony prices will probably prevent them from coming fully on-stream any time soon. The NDS will be selling antimony for a few more years, thus remaining as a small but readily available part of domestic supply.

ARSENIC

By Robert G. Reese, Jr.

Domestic survey data and tables were prepared by Mahbood Mahdavi, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

As has been the case since 1985, the United States had no domestic production of arsenic in 2000 and, consequently, remained dependent on imports to meet its arsenic needs. Although the United States imported some arsenic metal, most domestic arsenic imports were in compound form, primarily arsenic trioxide. China remained the principal supplier of arsenic and its compounds to the U.S. market.

Legislation and Government Programs

The U.S. Geological Survey (USGS) in 2000 was directly involved in a broad range of national and international studies related to arsenic and its distribution and mobility in the environment. Activities included data collection, long-term assessments, ecosystem analysis, predictive modeling, and process research on the occurrence, distribution, transport, and fate of arsenic as well as the impacts of contaminants on biota. Much of this work was conducted in partnership with other Federal and State agencies.

The location and extent of arsenic occurrence in ground water across the United States was the subject of a USGS map published in 2000 (Focazio and others, 2000). The presence of arsenic in ground water is largely due to minerals dissolving naturally over time as rocks and soils weather. Data on nearly 19,000 samples of potable ground water used to develop the map indicated that the arsenic concentration was nearly always lower than the U.S. Environmental Protection Agency (EPA) standard of 50 micrograms per liter. Additionally, the USGS found that approximately 10% of the samples exceeded the more stringent World Health Organization standard of 10 micrograms per liter. At yearend, the EPA was in the process of designating a new drinking water standard for arsenic.

Additionally, the USGS published a map showing the distribution of arsenic in the Warrior coalfield in Alabama (Goldhaber and others, 2000). Using data from over 900 chemical analyses contained in the USGS National Coal Resources Data System, the authors found that the Warrior field contained higher levels of arsenic and a suite of other trace elements when compared to the average for all U.S. coal. The map used three-dimensional plots of Warrior coalbeds to show arsenic abundance and concentration.

Consumption

Trade data indicated that the United States, with an estimated demand of more than 24,000 metric tons (t) in 2000, probably remained the world's largest consumer of arsenic. The estimated value of arsenic consumed domestically during the year was approximately $25 million. More than 95% of the arsenic consumed was estimated to have been in compound form, primarily arsenic trioxide. The largest end use for arsenic trioxide was in the production of wood preservatives. The three principal producers of arsenical wood preservatives were Hickson Corp., Smyrna, GA; Chemical Specialties Inc., Harrisburg, NC; and Osmose Wood Preserving, Inc., Buffalo, NY. Osmose also produces arsenic acid that is used by the glass industry as a fining agent to disperse air bubbles. Arsenic also was used in some herbicides for weed control.

Arsenic metal was used as an additive to improve corrosion resistance and tensile strength in copper alloys and as a minor additive (0.01% to 0.5%) to increase the strength of the posts and grids in some lead-acid storage batteries. An estimated 40 t of high-purity arsenic metal (99.9999%-pure or higher) was used in the manufacture of gallium arsenide, a semiconductor used in various electronic devices including wireless phones and high-speed computers.

Arsenic in the 20th Century

In 1901, the United States began production of arsenic trioxide, with an output of approximately 270 metric tons. Previously, the U.S. was import dependent, relying on shipments from Canada and Europe. U.S. imports of arsenic metal, arsenic trioxide, and arsenic sulfides in 1901 totaled 3,170 tons. Arsenic was used primarily as a herbicide, insecticide, and pesticide. During the century that followed, U.S. arsenic production and use changed significantly. For a number of years, the United States was the world's largest arsenic producer. Because of its toxic nature, however, various rules and regulations were enacted, especially in the 1970s, to eliminate or curtail human exposure to arsenic. Consequently, U.S. production of arsenic declined significantly, from a high of 32,700 tons in 1944 to 2,200 tons in 1985, when the sole domestic refiner ceased production.

By the end of the century, the United States no longer produced arsenic and was import dependent. About 20,000 to 30,000 tons per year of arsenic was imported in the late 1990s, mostly in the form of arsenic compounds. During 2000, China was the largest supplier of arsenic to the United States, accounting for most imports of arsenic trioxide. Nearly all of the arsenic consumed domestically was used as a preservative in the production of pressured-treated wood.

Digitized by Google

World Review

Arsenic trioxide was recovered from the smelting or roasting of nonferrous metal ores or concentrates in at least 16 countries in 2000. High-arsenic smelter or roaster dusts and residues that usually are not processed to commercial-grade trioxide were recovered in several other countries as well as at plants in countries producing commercial-grade material. Much of this material was stockpiled and could be available for future processing. Most countries did not report their arsenic production, and world production values had a high degree of uncertainty. China apparently remained the world's largest producer in 2000.

Commercial-grade (99%-pure) arsenic metal, produced through the reduction of arsenic trioxide, accounted for most world arsenic metal output. China accounted for nearly all the world's production of commercial-grade arsenic metal.

Worldwide, approximately 10 companies produced high-purity arsenic metal for use in the semiconductor industry.

Outlook

Despite environmental regulations that led to global disruption of production during the last decades of the 20th century, new sources of supply have emerged to fill the void. Given the abundance of arsenic in various waste streams, including nonferrous metal processing, world supplies of arsenic trioxide are expected to remain adequate to meet projected needs.

Because most arsenic is consumed as a compound in the production of arsenical wood preservatives used in home construction and renovation, arsenic demand is expected to correlate with changes in this market. In the short term, prohibitions on the use of arsenical wood preservative in certain applications is not expected to have any significant impact on demand. However, these prohibitions combined with the greater acceptance of alternative preservatives may reduce long-term demand.

Continued growth in the use of maintenance-free automotive batteries that require little or no arsenic will lower the demand for arsenic metal in this application; this decline, however, is likely to be offset somewhat by the consumption of arsenic to manufacture semiconductors.

ASBESTOS

By Robert L. Virta

Domestic survey data and tables were prepared by Shantae F. Hawkins, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Asbestos is a generic name for six fibrous minerals that have been used in commercial products. The six types of asbestos are chrysotile, crocidolite, amosite, anthophyllite asbestos, tremolite asbestos, and actinolite asbestos. Several properties that make asbestos so versatile and cost effective are high tensile strength, chemical and thermal stability, high flexibility, low electrical conductivity, and large surface area. Nearly all of the asbestos produced worldwide is chrysotile.

Legislation and Government Programs

The Occupational Safety and Health Administration (OSHA) solicited public comments on its information-collection requirements under its asbestos in general, shipyards, and construction standards. At issue are the quality of the information, ways to minimize the burden on employers, and whether or not the information collection is necessary and the burden has been correctly estimated (U.S. Department of Labor, 2000a, b, c).

The Environmental Protection Agency (EPA) increased coverage of State and local government employees under its asbestos worker protection rule (WPR) by incorporating OSHA's asbestos standards into the WPR. State and local government employees performing construction work, custodial work, and automotive brake and clutch repair work now are covered to the same extent as private sector workers. The WPR is cross-referenced to the OSHA asbestos standards for construction and for general industry so future amendments to the OSHA rules will also amend the WPR. Also, EPA's asbestos-in-schools rule was amended so that employees of local public education agencies who perform operations, maintenance, and repair activities under the asbestos-in-schools rule now are covered under the WPR (U.S. Environmental Protection Agency, 2000).

The EPA continued to test for the presence of asbestos in and around a vermiculite mine in Libby, MT. The agency has sampled indoor air, soil, dust, and insulation for asbestos. It began conducting more extensive sampling in March 2001. The agency also has completed some preliminary health studies on local residents and former workers at the vermiculite operation (U.S. Environmental Protection Agency, February 22, 2001, Libby Community Advisory Group, accessed March 8, 2001, at URL http://www.epa.gov/region8/superfund/libby/cag2-22.html#drl).

Following the controversy over Libby, MT, the Mine Safety and Health Administration inspected Virginia Vermiculite Co.'s mine in Virginia to determine asbestos levels. Air monitoring was conducted, and asbestos was not detected using the required sampling and analysis protocol. There remains a controversy, however, over how the samples were analyzed and

Asbestos in the 20th Century

Prior to 1900, U.S. demand for asbestos was less than 10,000 metric tons per year because technological development had not yet created large markets for asbestos. In 1900, though, U.S. demand had reached 20,000 tons and was growing. The expanding automotive and building industries provided ready markets for asbestos in the early 1900s. Demand for such items as asbestos brake shoes and clutches, asbestos-cement products, asbestos flooring, asbestos packings and gaskets, and asbestos thermal and electrical insulation grew rapidly. By 1950, 660,000 tons of asbestos was used by domestic manufacturers, making the United States the largest user of asbestos in the world. With the expansion of the economy after World War II, demand for asbestos continued to increase, reaching 801,000 tons by 1973.

In 2000, U.S. demand for asbestos returned to levels achieved in the late 1800s, about 14,600 tons or only 1.8% of the 1973 demand. The collapse in U.S. markets for asbestos began in the early 1970s in response to health and liability issues. First, it became well established that excess exposures to asbestos could result in the development of asbestosis and lung cancer, prompting the filing of large class-action suits against mining companies and manufacturers of asbestos products on behalf of workers suffering from these diseases. Second, strong public opposition to the use of asbestos began to affect sales of asbestos products and influence legislation dealing with asbestos. As a result, U.S. demand for asbestos plummeted as manufacturers either ceased production of asbestos-containing products, began using asbestos substitutes, or replaced asbestos-containing products with ones that did not contain asbestos. Asbestos markets, which took more than 100 years to peak, completely reversed themselves in less than 25 years. The decline in demand resulted in major shifts in the use of asbestos. The major uses for asbestos in 2000 were roofing products, gaskets, and frictions products, with 62%, 21%, and 12% of the market, respectively compared with 1973 when major markets were asbestos-cement pipe (24%), flooring (22%), roofing (9%), friction products (brakes and clutches) (8%), and packing and gaskets (3%).

Digitized by Google

whether the current methodology and exposure levels adequately protect the workers from exposure to asbestos (Industrial Minerals, 2000d; North American Minerals News, 2000b).

A variety of asbestos-containing products, such as brakes, gaskets, and asphalt roofing products, are used by the military on vehicles, ships, and missiles and in construction. Strategic-grade asbestos is not required in the manufacture of these products, and classified applications in which strategic-grade asbestos is used are believed to be minimal. The U.S. Department of Defense disposed of alls of the strategic- and nonstrategic-grade amosite, chrysotile, and crocidolite from the national defense stockpile in 2000.

Production

KCAC Inc. in San Benito County, CA, was the only company mining asbestos in the United States in 2000. The company mined a highly sheared serpentinite containing matted, short-fiber chrysotile and unfractured serpentinite (also called a mass-fiber deposit). Domestic production (sales) decreased by 27% to 5,260 metric tons (t) in 2000 from 7,190 t in 1999 (table 1). Domestic production data for asbestos were collected by means of a voluntary survey of the one domestic mining operation, representing 100% of the sales data shown in table 1.

Consumption

U.S. consumption of asbestos was 14,600 t, 8% less than that of 1999. The three leading domestic markets were roofing products, gaskets, and friction products, with 62%, 22%, and 12%, respectively, of the asbestos market. Essentially all of the asbestos used in manufacturing in the United States was chrysotile; 94% was grade 7, followed by grades 6, 5, 4, and 3, in decreasing order of consumption. A few tons of crocidolite may still be used for specialized applications, but this cannot be verified (table 2).

Prices

The average unit value of domestically produced asbestos increased from that of 1999. The average U.S. customs unit value for imported crude chrysotile decreased by 14% to $118 per metric ton in 2000. The average unit value for imports of spinning-grade chrysotile was $1,470 per ton, a 13% increase from that of 1999. Low-tonnage, high-value imports from South Africa and Zimbabwe caused the increase in the unit value. The unit value of the other grades of chrysotile decreased by 2% to $163 per ton in 2000. Imports of chrysotile from South Africa and Zimbabwe had the highest unit values. The average unit value of chrysotile imported from South Africa was $1,930 per ton and from Zimbabwe was $2,050 per ton (table 6).

The U.S. customs unit value for the crude and spinning grades of chrysotile fiber from Canada were $118 and $184 per ton, respectively (tables 3 and 6). Imports of "Other, chrysotile" from Canada were valued at $159 per ton (tables 3 and 6). Crocidolite imports reported by the U.S. Census Bureau were valued at $108 per ton (see discussion under Foreign Trade concerning crocidolite imports).

Prices ranged from $135 to $1,168 per ton for Canadian chrysotile and $200 to $440 per ton for South African chrysotile, depending on the grade (Industrial Minerals, 2000b). Quoted prices should be used only as a guideline because actual prices depend on the terms of the contract between seller and buyer.

Foreign Trade

The export free alongside ship (f.a.s.) value of asbestos fibers and products containing asbestos or asbestos substitutes increased by 21% to $296 million in 2000 from $245 million in 1999. Exports of brake linings, pads, and mounted brake linings accounted for most of this increase.

Mexico and Japan were the leading importers of asbestos fiber from the United States. Canada was the leading importer of U.S. products manufactured using asbestos or asbestos substitutes, followed by Germany, Mexico, Japan, and the United Kingdom (table 4). These five countries accounted for 81% of the value of asbestos products exported from the United States.

Exports and reexports of brake linings, disk pads, and mounted brake linings accounted for 87% of the value of all manufactured asbestos products (table 5). Products in these categories composed 94% of the value of goods manufactured using asbestos and asbestos substitutes that were exported to Canada, 95% of that exported to Mexico, 99% of that exported to Germany, and 91% of that exported to Japan.

In 2000, approximately 18,800 t of asbestos was exported, according to the U.S. Census Bureau. The exports included asbestos crudes, fiber, sand, refuse, and stucco. Exports of domestic origin were estimated to be approximately 5,000 t. Reexports of Canadian fiber accounted for the bulk of the remaining exports (mainly through New York), although some manufactured products and nonasbestos mineral exports may have been included in the 18,800 t.

In 2000, Canada supplied 99% of the asbestos imported by the United States. Imports also were reported from South Africa (53 t) and Zimbabwe (54 t) (table 6). The U.S. Census Bureau reported 67 t of crocidolite imported in 2000. Based on its unit value and country of origin (Canada), it is likely that the asbestos was chrysotile rather than crocidolite. Chrysotile composed more than 99% of the asbestos imported into the United States in 2000.

The United States also imported $166 million of asbestos products. This includes approximately 51,500 t valued at $26.3 million of asbestos- and cellulose-fiber cement products (A/C), including panels, pipe, and tile. The bulk of the A/C products was imported in the form of flat sheets and panels (92%), followed by corrugated sheet (3%), pipe (1%), and other (4%).

World Review

World production of asbestos was estimated to be 1.9 million metric tons. Russia continued to be the leading producer of asbestos, followed by Canada, China, Brazil, Kazakhstan, and

Digitized by Google

Zimbabwe. These countries accounted for 93% of the world production (table 7).

The controversy over the use of asbestos continued to be the focus of attention worldwide. Bans have already been enacted in many European countries. In 2000, Saõ Paulo became another of several Brazilian cities that enacted an asbestos ban. Chile began drafting legislation to ban the use of asbestos, with certain exceptions. This was subsequently enacted in 2001 (International Ban Initiative Secretariat, February 15, 2001, Chile bans asbestos, accessed March 27, 2001, at URL http://www.btinternet.com/~ibas/Frames/F_LKA_Chile_Ban.htm).

Canada.—Production of chrysotile from the Cassiar Magnesium Inc. operation in British Columbia, which began in January 2000, has been suspended following a fire in the mill facility. Damage is being evaluated but a date for resuming operations has not been set. The company marketed its chrysotile internationally with customers in Dubai, India, Indonesia, Iran, Japan, Sri Lanka, and Thailand. Plans are in place for the installation of a wet-processing plant that would bring annual capacity to 50,000 metric tons per year (t/yr). Cassiar Magnesium is proceeding with its development of a facility to process serpentine tailings for magnesium. Metal production is not anticipated until 2003 or 2004 (North American Minerals News, 2000a; Canada NewsWire, December 27, 2000, Cassiar mill damaged by fire, accessed December 30, 2000, at URL http://www.newswire.ca/releases/December2000/27/c6332.html).

France.—The World Trade Organization (WTO) upheld France's decision to ban asbestos use. The ruling was based on WTO guidelines for health protection, which superseded its free trade rules. The Canadian Government announced that it will appeal the decision on grounds that the ban may not comply with trade agreements (Industrial Minerals, 2000a; Morrison and Williams, 2000).

Russia.—Uralasbest, the leading Russian asbestos producer, announced plans for installing a 50,000 t/yr magnesium plant at its operation in Sverdlovsk. The plant will cost $300 million and will process serpentine tailings from the asbestos operation. Uralasbest will use the technology developed by Solikamsk Magnesium Plant, a leading Russian magnesium producer. Solikamsk, which has been producing magnesium from carnallite, announced plans to use asbestos tailing from Uralasbest's Bazhenovskoye asbestos mine (Mining & Metals Report, 2000).

Uralasbest sought an exclusion from new import custom duties on asbestos from the Russian Parliament. The new rate will be 30% higher than previously. Uralasbest, which payed its wages in arrears and reduced its tax indebtedness in 1999, also faces opposition to the use of asbestos and erratic production resulting from power outages (Industrial Minerals, 2000c).

Outlook

Domestic markets for asbestos probably will remain unchanged or decline only slightly over the next few years. Friction products, gaskets, and roofing products will continue to be the only significant domestic markets of asbestos for the foreseeable future in the United States. The slow recovery of the Southeast Asian economies and continued efforts to ban asbestos use worldwide are likely to result in a slight downturn in sales worldwide.

BARITE

By James P. Searls

Domestic survey data and tables were prepared by Jeff Milanovich, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

Barite, a name that was derived from the Greek word "barys" (heavy), is the mineralogical name for barium sulfate. In commerce, the mineral is sometimes referred to as "barytes." As used in this report, the term "primary barite" refers to the first marketable product, which includes crude barite (run of mine) and the products of simple beneficiation methods, such as washing, jigging, heavy media separation, tabling, flotation, and magnetic separation. Most crude barite requires some upgrading to minimum purity or density. Barite that is used as an aggregate in a heavy cement is crushed and screened to a uniform size. Most barite is ground to a small uniform size before it is used as a filler or extender, an addition to industrial products, or a weighting agent in petroleum well-drilling mud [American Petroleum Institute (API) or Oil Companies' Materials Association (OCMA)] specification barite. Barite used for drilling petroleum wells can be blue, black, buff, brown, or gray depending on the ore body. It must be finely ground so that at least 97% of the material, by weight, can pass through a 200-mesh (75-micrometer) (Tyler) screen, and no more than 30%, by weight, can be less than 6 micrometers in effective diameter, which is measured using sedimentation techniques. The ground barite also must be dense enough that its specific gravity is 4.2 or greater, soft enough to not damage the bearings of a tricone drill bit, and both chemically inert and containing no more than 250 milligrams per kilogram of soluble alkaline salts (American Petroleum Institute, 1993, p. 6-11). A small percentage of iron oxide is allowable. An additional feature of barite is noninterference with magnetic measurements taken in the borehole, either during logging while drilling or in separate drill-hole logging. In offshore drilling, the U.S. Environmental Protection Agency limits the content of mercury to 1 milligram per kilogram of barite and that of cadmium to 3 milligrams per kilogram of barite (U.S. Environmental Protection Agency, 1997). Although barite contains a heavy metal (barium), it is not a toxic chemical under section 313 of the Emergency Planning and Community Right-to-Know Act of 1986 because it is very insoluble.

Production

Domestic sales data for barite were derived from voluntary responses to a survey of U.S. operations and follow-up telephone calls by the U.S. Geological Survey. Barite production for 2000 was 392,000 metric tons (t), about 9% below that of 1999. Of the known 31 operations, 16 responded to survey forms, and 15 responded by telephone. Nine mines were included in the survey; six were producing, and three were idle. Of the producing mines, three were in Nevada, two were in Georgia, and one was in Tennessee; two idle mines were in Nevada, and one was in Missouri. There were 24 mills/grinding plants operating for the report year, and an additional plant was being refurbished. Three plants were in Nevada, all associated with mines (one mine was idle). Two grinding plants in Georgia were associated with mines, and two plants in Illinois

Barite in the 20th Century

At the beginning of the 20th century, barite was a mineral of minor importance to the United States. Its primary use was to extend lead oxide in white paint. Barite also added the special qualities of hiding power and flatness. Because white lead sometimes turns black or yellow and barite does not, ground barite became a pigment on its own merit. Barite was also converted to other barium chemicals. Barium chloride was added to bricks before firing to stop efflorescence when exposed to weather. Barium chemicals were used for refining sugar, enameling iron, making oilcloths and paper collars, and in the manufacture of paper, artificial ivory, rubber, and lithopone. Barium carbonate or nitrate adds luster and brilliance to glass. Lithopone became a major paint ingredient in the 1920s; its use lasted into the 1950s, peaking at 150,000 metric tons per year of barite in both 1937 and 1947 entering the manufacture of lithopone. Later in the century, however, titanium dioxide replaced lead oxide, barite, and zinc oxide in the coating industry. Another barite use was patented in 1926 by the oil well drilling industry.

During the later part of the century, barite was used in the drilling mud of oil and gas wells, particularly for wells deeper than 2,000 meters, and petroleum-well-drilling demand for barite became the mineral's major end use during economic expansions after World War II and the subsequent increased use of oil and gas in the United States. The profitability of oil and gas production had a strong effect on the number of drill rigs, and the number of drill rigs had a strong effect on the consumption of barite. The United States was the leading petroleum well drilling country starting in 1970, reaching 4,530 drill rigs in December 1981, and was the largest consumer of barite. Record highs of about 2.6 million tons of barite produced and 4.3 million tons consumed in the United States were reported in 1981. Barite production and consumption declined since then to 400,000 tons produced, 2.1 million tons imported into the United States, and 6.2 million tons produced worldwide in 2000. Barite industrial end uses accounted for an estimated 78,000 tons per year in the United States.

Digitized by Google

used imported crude barite. One grinding plant in California was associated with a mine in Nevada, and one grinding plant in Missouri used material from a stockpile from a nearby idle mine. Five of the six active mines had grinding plants. There were 15 facilities on the Gulf of Mexico that produced API-grade barite in 2000; an additional plant was undergoing renovation in Morgan City, LA. These grinding plants received relatively low priced crude barite from China and India for grinding to petroleum-well-drilling specifications and small amounts for filler and extender markets. In Texas, there were two plants in Brownsville, three in Corpus Christi, one in Galveston, and two in Houston. In Louisiana, there was a grinding plant in Houma, two near Lake Charles, one in New Iberia, one near Morgan City, and two near New Orleans. At yearend, one plant in New Orleans was relocated to Morgan City. Baker Chemical, Inc., closed and sold its two plants.

The quantity of primary barite sold or used by producers fell by about 10% from that of 1999, and weighted average prices declined by about 5%. Less than 4% of barite sales from domestic producers were for industrial end uses. The remaining sales were for petroleum-well-drilling API-specification markets. None of the Nevada-mined ore was sent to the coast of the Gulf of Mexico for grinding. High quality lump barite entered the country for several filler and extender grinding plants in the Midwest United States.

Halliburton Co. owned the Baroid Drilling Fluids Division. A joint venture between Smith International Inc. and Schlumberger Ltd. owns M-I LLC, which owns M-I Drilling Fluids. The third major U.S. barite company was Baker Hughes Inteq, a division of Baker Hughes, Inc. These three companies mined barite in Nevada and in countries with collocated beneficiation plants (mills) and grinding plants, along with the above-mentioned grinding plants in Louisiana and Texas. Excaliber Minerals, Inc., a division of Newpark Resources Inc., has become significant in the imported barite grinding industry in Louisiana and Texas.

These four companies on the Gulf of Mexico received imported barite that was transported by ship to Louisiana and Texas shores. These Gulf of Mexico locations are closer to the large offshore drilling rigs in the Gulf of Mexico and the clusters of onshore areas of exploration and significant discoveries (plays) in the Petroleum Administration for Defense District 3 (where searching for gas and oil is most profitable).

The outputs of crushers and grinders in Louisiana increased by more than 34%, while the outputs of crushers and grinders in Texas increased by nearly 157% (table 2). Industrial end-use sales by crushers and grinders of domestic production and imported barite in 2000 was essentially unchanged (table 3).

These four producers and other smaller companies import and grind or crush barite for drilling mud. Two smaller companies mine and beneficiate barite for the filler and the extender and chemical industries in Georgia, and a small mine and a mill operate in Nevada and California for the same end use. Two companies import or purchase domestic barite for grinding in Illinois for the Midwest filler and extender and chemical industry markets. The Quincy, IL, grinding plant owner changed its name to Elementis Pigments Inc. from Harcros Pigment Inc.

Trade

Domestic exports were about 36,000 t, mostly to Canada (table 4). Imports of Chinese barite increased by nearly 200% above that of 1999 to equal about 93% of total barite imports of 2.1 million metric tons (Mt). Imports from India declined by more than 25% from those of 1999 to 101,000 t (table 5).

Consumption

Barite apparent consumption increased by about 91% compared with that of 1999 to less than 2.5 Mt. Ground barite sales climbed by about 53% to 2.1 Mt. Barite imports during 2000 were up by 140% to 2.1 Mt from 870,000 t.

Since 1975, about 90% of the consumption of barite has been used during the operation of drill rigs to explore for, discover, develop, and expand petroleum reserves. Often the demand for drill rigs to explore and develop petroleum reserves rises as the prices of oil and gas rise. For the oil-directed rigs, the average futures price of light sweet west Texas crude started the year at about $26.30 per barrel for the last day of December 1999; rose to about $32.10 per barrel, as reported for June 28; and declined to around $29.00 per barrel, as reported for December 15, 2000 (Oil & Gas Journal, 2000-2001). Oil-directed drill rigs in the United States increased to around 205 rigs between April through late August from about 130 rigs in late January and then rose to about 245 rigs in mid-December. For the year, this increase was a mild increase, where the oil-directed rigs rose from about 18% of total rigs to about 21% of total rigs in response to the oil price increase. For the gas-directed rigs, the futures price for natural gas was about $2.34 per million British thermal units on the last day of December 1999 and rose to $8.18 per million British thermal units in mid-December 2000 (Oil & Gas Journal, 2000-2001). Gas-directed rigs in the United States increased to 862 rigs in mid-December 2000 from 624 rigs on the last day of December 1999. The gas-directed rig count change was also mild and declined slightly to about 79% of total rigs from 82% in response to the gas price increase (Oil & Gas Journal, 2000-2001).

The reason for the increase in the number of oil-directed rigs seems to have been that drilling for oil, in contrast to 1998, was once again a profitable investment, as described by the Herold 34th annual replacement reserve cost analysis (Cacchione and Johnson, 2001). According to the Herold study, proven oil reserves "of the top 50 companies based upon size of U.S. proved reserves (among public companies that have filed SEC[1] disclosures by April 13, 2000)" increased by 9.4% [1.5 billion barrels (Gbbl)] from the beginning-of-the-year 15.9 Gbbl by extensions and discoveries (drilling) at a cost of about $5.17 per barrel of oil equivalent in 2000 (Cacchione and Johnson, 2001). This was a significant decrease from the $13.04 per barrel of oil equivalent for 1998 that drove down the use of drill rigs and barite in 1999. The oil companies also "increased reserves by 22.6% or 3.6 Gbbl by 'purchase of reserves'," which cost about $4.73 per barrel of oil equivalent. The top 50 oil companies probably increased drilling, and there was also an increase in drilling from the smaller independents who had money to search for more oil reserves having sold their proven reserves to the larger, integrated companies.

Digitized by Google

According to the Herold study, proven gas reserves for their 50 biggest companies increased for the year 2000 to 102 trillion cubic feet from 86.8 trillion cubic feet (Cacchione and Johnson, 2001). There was a 13% increase, 11.3 trillion cubic feet, in reserves from 86.8 trillion cubic feet at the beginning of the year by extensions and discoveries (drilling) and 16.8% or 14.6 trillion cubic feet from 86.8 trillion cubic feet by purchase of reserves. Production was 10.0 trillion cubic feet with end-of-year proven gas reserves of 102 trillion cubic feet. "For the first time in 5 years extensions and developments outpaced gas production" (Cacchione and Johnson, 2001). There was also 1.1 trillion cubic feet of improved recovery and 1.4 trillion cubic feet of [reserve] revisions. The same analysis reported that finding and development costs (drilling), not broken down by oil and gas, fell to $5.17 per barrel of oil equivalent in 2000 from $5.31 per barrel of oil equivalent in 1999 and $13.04 per barrel of oil equivalent in 1998. Gas rigs continued to account for about 80% of the total rig count, staying between 74.6% and 82.6% for the year in the United States.

Drilling for oil and gas was more successful and continued to be rewarded by higher prices all through the year (Cacchione and Johnson, 2001). Results for individual companies varied widely, though. For example, BP Amoco, the biggest capital investor in the U.S. petroleum market for the year, spent $3.5 billion in finding and development. At its oil operations, BP Amoco produced 251 million barrels (Mbbl) of oil but revised its oil reserves downwards by 167 Mbbl for a total reserve reduction of 418 Mbbl for the year. At its gas operations, BP Amoco added 1.9 trillion cubic feet of natural gas reserves by extensions and discoveries, improved recovery, and reserve revisions, all products of drilling. BP Amoco also had a 0.4-trillion-cubic-foot final increase after gas reserve purchases of proven property, sales of property, and production of gas for the year. Not all companies had these results, but when summed, the top 50 petroleum companies achieved a 163% reserve replacement rate of oil production by drilling and a 138% reserve replacement rate of gas production by drilling.

Prices

The nominal average weighted sales price for primary barite from mines and associated beneficiation plants in the United States decreased slightly to about $25.10 per ton in 2000. Nominal average prices for crushed and ground barite decreased by 4% to $75.80 per ton compared with those of 1999. The weighted average prices of the production from "other" regions declined by about 11% while Louisiana and Texas prices were relatively unchanged.

According to Industrial Minerals (2000b), midyear international barite prices were as follows:

- API, lump, cost, insurance, and freight (c.i.f.) [U.S.] Gulf Coast, Chinese, $43 to $45 per ton; Indian, $45 to $48; Moroccan, $50 to $52.
- Unground, OCMA/API, bulk, specific gravity 4.2, free on board (f.o.b.) Morocco, $39 to $41 per ton.
- Ground, bagged, specific gravity 4.22, f.o.b. Morocco, $75 to $85 per ton.
- Ground, OCMA/API, big bags (1.5 tons) f.o.b. south Turkey, $68 to $70 per ton.
- Ground, OCMA, bulk, delivered Aberdeen [United Kingdom], $75.61 to $83.17[2] [£50 to £55] per ton; delivered Great Yarmouth [United Kingdom], $87.71 to $98.29 [£58 to £65] per ton.
- Micronized, off-white, minimum 99%, less than 20 micrometers, delivered United Kingdom, $211.71 to $226.83 [£140 to £150] per ton.
- Ground, white, paint-grade, 96% to 98% barium sulfate ($BaSO_4$), 350 mesh, 1 to 5 tons delivered United Kingdom, $294.88 to $332.68 [£195 to £220] per ton.

World Review

Since 1975, about 90% of consumed barite has been used with drill rigs to explore for, discover, develop, and expand petroleum reserves. Often the demand for drill rigs to explore and develop petroleum reserves rises as the prices of oil and gas rise. On the last day of December 1999, the futures price of west Texas light sweet crude was about $26.30 per barrel and Brent 38° crude was also about $26.30 per barrel (Oil & Gas Journal, 2000-2001). Oil prices peaked in November 2000, with the west Texas light sweet crude at about $35.25 per barrel and Brent 38° crude reaching about $33.40 per barrel.

According to the world drill rig reports, which do not cover most of the former and present centrally planned economies, the world drill rig count (with Canadian onshore drill rigs subtracted because their operations are strongly seasonal) rose to about 1,810 rigs at the end of 2000 from about 1,340 at the beginning of 2000 and about 1,100 rigs in April 1999 [Oil & Gas Journal, 2000-2001 (the third issue of each month)]. It would seem that barite consumption around the world rose for the year but there is no confirming data at this time. In ascending order of rig count, the following regions had active drill rigs:

Africa.—The African active drill-rig count rose to about 49 rigs in December from about 39 rigs in January, primarily with offshore drill rigs. Barite consumption probably increased in that region.

Europe.—European drill rigs rose to 96 total rigs in October from 65 total rigs in January, reaching a peak in October of a 31 rig increase, primarily with offshore rigs, which increased to about 57 rigs in October from about 33 rigs in January. Barite consumption probably increased in that region.

Asia and the Pacific.—The drill-rig count in Asia and the Pacific rose to about 155 in October from about 130 in January and settled to about 145 in December. The onshore drill-rig count increased by about 15 rigs while the offshore drill-rig count increased by about 10 rigs. Barite consumption probably increased in that region.

Middle East.—The Middle Eastern drill-rig count rose to about 165 in December from about 140 in January, with onshore rigs increasing by about 20 rigs, and offshore rigs, by about 5 rigs. Barite consumption probably increased in that region.

Latin America.—Latin American rigs increased to about 265 rigs in October from about 185 rigs in January. There were about 210 rigs onshore and 55 rigs offshore in October in reaction to petroleum prices; then the rig counts decreased by about 3 rigs onshore and 5 rigs offshore by December. Barite consumption probably increased in that region.

---

[2]US$1.00=£0.6613

Digitized by Google

Canada.—Canadian drill rig usage started the year at about 500 rigs in January, fell to a low of about 145 rigs in April, and recovered to about 410 active drill rigs in December. Canada went from a peak of 507 in February 1998 to a peak of 332 in February 1999 (and a low of 62 rigs in April), 544 in February 2000, and 562 in February 2001. Barite consumption probably increased in that region. Canada has a pattern of a high drill-rig count in the winter and a low drill-rig count in the spring in normal times. Canada is also an important gas supplier to the United States.

The major barite-producing countries, other than the United States, for which information was available were as follows:

China.—The producing mines are clustered in the south of China in Guangxi Province with 53% of production, which includes Nanning City; Hunan Province with 13% of production, which is north-by-northeast of Guangxi; and Guizhou Province with 13% of production, west of Hunan, and north-by-northwest of Guangxi (Newcaster, 2000). Guandong Province, with 9% of production, is east and up the southern coast of China and includes Hong Kong. Fujian Province, with 8% of production, is also on the coast to the northeast of Guandong Province and includes Fuzhou City. In 1997, a duopoly of "[t]he large two government owned" sellers forced up the price of barite in China, and in early 1998, when the demand for drilling started to falter due to low oil and gas prices in the United States and elsewhere, the duopoly kept mining and sending undergrade ore to the ports. In 1999, mining stopped, and port traders were caught with undergrade ore and no market (Newcaster, 2000). A new, more workable relationship with "[a]t least a dozen potential producers [who] are seeking direct supply agreements" was formed in 2000, when demand reawoke and barite grinders needed ore that met grade specifications.

Mexico.—"Chemical Products Corp. (CPC) of Cartersville, GA, owns the barytes producer Minas de Barita, which purchased Barita de Sonora S.A. at the end of 1997. Barita de Sonora is still not in production but CPC is carrying out feasibility studies to confirm the potential for chemical grade barytes production. No drilling grades will be produced" (Crossley, 2000, p. 70).

India.—A state entity controls the largest Indian barite source in Andhra Pradesh Province by annually leasing the mine source to the highest bidder (Newcaster, 2000). In fiscal year 1997-98, the successful bidder won with a bid that was too high for a market clearing price, and little barite left the country. In fiscal year 1998-99, India shipped barite to the United States with competitive prices. In fiscal year 1999-2000, Indian production was slowed down owing to government/trader/management disagreements and labor strikes.

Russia.—A new mine was opened in the Vorkuta district of the Komi Republic and was named the Khoilinsky deposit (Industrial Minerals, 2000a). The mine was reported to be near the eastern Siberian oil/natural-gas provinces with ores of more than 90% barite and enough reserves for 120,000-metric-ton-per-year production for more than 20 years. There was no mention of color or heavy metal occurrence or lack thereof.

Thailand.—Minerals traders in Thailand have started to deliver barite to the world market, reportedly using Thailand and Laotian material (Newcaster, 2000).

Outlook

In the United States, the gas industry looks more viable and profitable in the exploration and development departments and could be a market for barite consumption for many years. The amount of imported natural gas or substitute will indicate the health of this market in the future. The oil industry has returned to profitability with oil reserves that were found, as finding and developing costs per barrel of oil equivalent contracted down to normal levels. However, it may be that the barite-for-drilling-mud market will slowly move away from the United States over the long term as more petroleum fuel is imported into the United States and less is produced or as some other energy source replaces petroleum products in some end uses. The four barite suppliers will continue to support drilling activity as those centers of activity move to Africa, the Asia-Pacific region, and the former Soviet Union.

BAUXITE AND ALUMINA

By Patricia A. Plunkert

Domestic survey data and tables were prepared by Micheal George, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Bauxite is a naturally occurring, heterogeneous material comprised primarily of one or more aluminum hydroxide minerals plus various mixtures of silica (SiO_2), iron oxide (Fe_2O_3), titania (TiO_2), aluminosilicates (clay, etc.), and other impurities in trace amounts. The principal aluminum hydroxide minerals found in varying proportions within bauxite are gibbsite [$Al(OH)_3$] and the polymorphs, boehmite and diaspore [both AlO(OH)].

Bauxite is typically classified according to its intended commercial application, such as abrasive, cement, chemical, metallurgical, and refractory. Of all bauxite mined, approximately 85% is converted to alumina (Al_2O_3) for the production of aluminum metal, an additional 10% goes to nonmetal uses as various forms of specialty alumina, and the remaining 5% is used for nonmetallurgical bauxite applications. The bulk of world bauxite production is, therefore, used as feed for the manufacture of alumina via a wet chemical caustic leach process known as the Bayer process. The majority of the alumina produced from this refining process is smelted using the Hall-Héroult process to produce aluminum metal by electrolytic reduction in a molten bath of natural or synthetic cryolite ($NaAlF_6$).

Specifications for the nonmetallurgical grades of bauxite are more stringent than those for bauxite used to produce metal and are based on the processing requirements and special properties required of their final commercial products. The natural chemical impurities that exist within these specialty-grade raw materials are not chemically removed by refining as is the case for metallurgical-grade bauxite. Nonmetallurgical ores in an essentially unrefined chemical form are used as direct feed for the production of their ultimate end products. Although figures on bauxite production and consumption within nonmetallurgical markets are not commonly available, the principal industrial end uses for nonmetallurgical-grade bauxite are considered to be in refractories and abrasives, followed by cement applications. In addition, the aluminum chemicals and steel industries also consume significant quantities of bauxite.

In 2000, 22 countries reported bauxite mine production, and total world production increased by 6% compared with that of 1999. Australia, Brazil, Guinea, and Jamaica accounted for about 70% of the total bauxite mined in 2000. The principal sources of nonmetallurgical-grade bauxite are limited to only a handful of countries: abrasive grade is produced in Australia, China, Greece, Guinea, Guyana, and Italy; refractory grade, in Brazil, China, and Guyana (Russell, 1999, p. 49, 58).

Total reported world reserves of bauxite are sufficient to meet cumulative world primary aluminum metal demand well into the 21st century. Although bauxite reserves are unevenly

Bauxite and Alumina in the 20th Century

In 1900, bauxite in the United States was mined in three States—Alabama, Arkansas, and Georgia. Production that year was about 23,600 metric tons. World bauxite production in 1900 totaled 88,000 tons and was derived from three countries; the largest producer was France (58,500 tons), followed by the United States and the United Kingdom (5,870 tons). Even in 1900, the United States was not self-sufficient in bauxite and imported 8,790 tons of bauxite, approximately 28% of U.S. consumption. Bauxite was used mainly for the manufacture of aluminum, although a considerable quantity was used for the manufacture of aluminum sulfate and crystalized alum. In order to produce aluminum commercially, bauxite was converted to alumina by the Bayer process, which was patented by Karl Josef Bayer in 1888 and is still used today. Data on domestic and world production levels of alumina in 1900 are not available. Reports, however, indicate that the Pittsburgh Reduction Company (Alcoa Inc.) operated an alumina plant in New Kensington, PA, in 1900.

In 2000, bauxite production in the United States was negligible and was used for nonmetallurgical applications. World bauxite mine production totaled about 135 million metric tons. Of the 22 countries that reported mine production, Australia, Brazil, Guinea, and Jamaica accounted for about 70% of the production. Of the bauxite mined worldwide, about 85% was converted to alumina by the Bayer process for producing aluminum metal. An additional 10% was used in nonmetallurgical applications in various forms of specialty alumina, and the remaining 5% was used for nonmetallurgical bauxite applications, such as abrasives, refractories, cement additives, and aluminum chemicals.

Domestic production of alumina in 2000 was derived almost exclusively from imported metallurgical-grade bauxite. An estimated 90% of the alumina shipped by U.S. refineries went to domestic primary smelters for aluminum metal production. Consumption by the abrasive, chemical, refractory, and specialty industries accounted for the remainder. Despite being one of the four largest alumina producers in the world, the United States depends on alumina imports for about one-half of its metallurgical requirements. Of the 28 countries that produced a total of more than 49 million tons of alumina, Australia dominated the industry and accounted for about one-third of total world production.

Digitized by Google

distributed throughout the world, with approximately 90% in about a dozen countries, the sheer magnitude of these reserves (25 billion metric tons) is sufficient to ensure a readily accessible supply for the future (Plunkert, 2001).

U.S. production of alumina (calcined equivalent), derived almost exclusively from imported metallurgical-grade bauxite, decreased by 7% in 2000 compared with that of 1999. An estimated 90% of the alumina shipped by U.S. refineries went to domestic primary smelters for aluminum metal production. Consumption by the abrasives, chemicals, refractories, and specialties industries accounted for the remainder of U.S. alumina shipments.

World output of alumina increased 5% in 2000. The principal producing countries, in descending order of alumina output, were Australia, the United States, China, and Jamaica. These countries accounted for almost 60% of the world's production; Australia alone accounted for about one-third of total world production.

Legislation and Government Programs

In September, the Defense Logistics Agency (DLA) released its Annual Materials Plan (AMP) for the National Defense Stockpile (NDS) for fiscal year 2001. The 2001 AMP, including its subsequent revisions, provided for the sale of 3.05 million metric tons (Mt) (3 million long tons) of metallurgical-grade bauxite, of which 2.03 Mt (2 million long tons) was Jamaica type and 1.02 Mt (1 million long tons) was Suriname type (Defense Logistics Agency, 2000a). Also, as part of the plan, the DLA was authorized to dispose of 5,080 calcined tons (5,000 long calcined tons) of refractory-grade bauxite in fiscal year 2001 (Defense Logistics Agency, 2001b). These were the maximum amounts recommended for disposal during the fiscal year, and the actual level of sales was to be dependent upon the prevailing market conditions.

During calendar year 2000, the DLA announced the following sales of bauxite from the NDS: 10,200 metric tons (t) (10,000 long tons) of metallurgical-grade bauxite, Jamaica type, for a provisional value of $45,000 to Bulk Materials International (Defense Logistics Agency, 2000b); and 680,000 t (669,000 long tons) of metallurgical-grade, Suriname type, for an estimated value of $5.11 million to Alcoa Inc. and Bulk Materials Inc. (Defense Logistics Agency, 2000c).

At yearend, the NDS uncommitted inventory for metallurgical-grade bauxite was 5.5 Mt (5.42 million long tons) of Jamaica type and 201,000 t (197,000 long tons) of Suriname type. The NDS calcined refractory-grade bauxite inventory was 2,520 calcined tons (2,480 long calcined tons) (Defense Logistics Agency, 2001a).

Production

On May 3, Alcoa Inc. and Reynolds Metals Co. announced that the U.S. Department of Justice (DOJ) and the European Union (EU) had approved their proposed merger and that the merger had been completed. Reynolds shareholders had approved the merger on February 11. Under the terms of the consent decree entered into with the DOJ and an undertaking agreement with the EU, Alcoa was required to sell a 25% interest in Reynolds' Longview, WA, smelter, as well as Reynolds' interests in three alumina refineries—Worsley, Australia (56%); Stade, Germany (50%); and Sherwin, TX (100%). As a result of the merger, each outstanding share of Reynolds common stock was converted into 1.06 shares of Alcoa common stock (Alcoa Inc., 2000a).

On June 1, Alcan Aluminium Ltd. and algroup, the aluminum division of Alusuisse Lonza Group Inc., announced that, following the approval of the DOJ and the EU, the companies had reached agreement on their merger plan (Alcan Aluminium Ltd., 2000a). The EU gave its approval subject to commitments made by the companies to alleviate the EU's competition concerns in the aluminium trihydrate (ATH) market. Among its commitments, Alcan proposed selling algroup's ATH facility in Martinswerk, Germany, and the algroup lithography operations in Bridgenorth, United Kingdom (Platt's Metals Week, 2000a). The merger, which involved the combination of a cash payment and the exchange of 17.1 Alcan common shares for every algroup share, was finalized on October 17 (Alcan Aluminium Ltd., 2000b).

Bauxite.—For many years, domestic mines have supplied less than 1% of the U.S. requirement for bauxite. Essentially all the domestic bauxite production is used in nonmetallurgical products, such as abrasives, chemicals, proppants, and refractories. Thus, the United States imports almost all the bauxite, especially the metallurgical grade, that it requires.

Alumina.—Alcoa sold its 1.6-million-metric-ton-per-year (Mt/yr) Sherwin alumina refinery located near Corpus Christi, TX, to BPU Reynolds, Inc., a private investment company. The sale of the former Reynolds facility was required under the DOJ regulatory approval that cleared Alcoa's acquisition of Reynolds (Alcoa Inc., 2000b). According to the Corpus Christi Caller Times, the name BPU Reynolds derives from its four principal investors: former Reynolds Metals vice chairman Randy Reynolds; Peter Bailey, a former Alcoa executive who managed Alcoa's Point Comfort alumina refinery and its alumina chemical sales; retired Alcoa sales executive Lewis Paterson; and Mark Uzelac, a former Westinghouse executive (Metal Bulletin, 2000b).

In July 1999, Kaiser Aluminum & Chemical Corp.'s 1.05-Mt/yr Gramercy, LA, alumina refinery was extensively damaged by an explosion in the digestion area of the plant. Repairs on the damaged part of the plant began during the first quarter of 2000. Initial production at the plant commenced during the middle of December 2000, and production was expected to increase progressively throughout 2001. At the end of February 2001, the plant was operating at 70% of its newly rated capacity of 1.25 Mt/yr. Construction at the facility was expected to be completed during the third quarter of 2001 (Kaiser Aluminum & Chemical Corp., 2001, p. 16).

Alcoa announced the temporary closure of its 600,000-metric-ton-per-year (t/yr) alumina refinery at St. Croix, U.S. Virgin Islands. The plant, which had been operating since December 1997 and sold alumina to Alcoa-operated smelters in the United States, ceased production at the end of January 2001 (Alcoa Inc., 2000d).

Digitized by Google

Consumption

Bauxite.—Total domestic consumption of bauxite decreased by about 9% compared with that of 1999. Most of the decrease in consumption was accounted for by the continued loss of alumina production at the damaged Gramercy refinery. In 2000, 95% of the bauxite consumed in the United States was refined to alumina (an estimated 2.1 t of dried bauxite was required to produce 1 t of alumina); the remaining 5% was consumed in nonmetallurgical applications (table 4). Domestic production and consumption data for bauxite and alumina were obtained by the U.S. Geological Survey from three separate, voluntary surveys of U.S. operations. Typical of these surveys is "Bauxite Consumption," sent to 47 operations, 34 of which responded, representing 75% of total bauxite consumption listed in table 4.

C-E Minerals Inc. purchased North American Processing Co., which was renamed C-E Minerals Processing. The 68,000-t/yr plant in Newell, WV, processes refractory minerals such as bauxite, brown fused alumina, magnesite, magnesia, and silicon carbide (Industrial Minerals, 2000a).

Resco Products Inc. entered the refractory brick market following the purchase of certain divested assets from RHI Refractories America Inc. Resco acquired the former Harbison-Walker Refractories Co. plants in Hammond, IN, and Marelan, Quebec, as well as a number of product lines from the RHI plant in Farber, MO, and the former Harbison-Walker facility in Windham, OH. The divestitures were required for U.S. Federal Trade Commission (FTC) approval of RHI's acquisition of Global Industrial Technologies, Inc., in 1999 (The Refractories Institute, 2000).

Having made the required FTC divestitures, RHI began restructuring its North American operations. In April, a $10 million capital improvement program, which included the addition of three new hydraulic brick presses, related support equipment, and a minor plant expansion, was begun at the Windham, OH, facility. Plants in Curwensville and Wolmelsdorf, PA; Farber, MO; and Northeast, MD, were closed (Industrial Minerals, 2000c).

Alumina.—An estimated 90% of the alumina shipped by U.S. alumina plants went to domestic primary aluminum smelters for metal production. In 2000, 23 primary aluminum smelters consumed 7.16 Mt of alumina. Consumption in various forms by the abrasives, chemicals, refractories, and specialties industries accounted for the remainder of U.S. alumina use.

Prices

Most metallurgical-grade bauxite and alumina are purchased under long-term contracts. Contract terms for these commodities normally are not made public. Spot prices for metallurgical-grade alumina and specialty forms of bauxite and alumina for nonmetallurgical applications, however, are published in trade journals.

Industrial Minerals (2000b) quoted end-of-year prices for several types of imported refractory-grade bauxite from China and Guyana. The price quotes for Chinese refractory-grade bauxite, minimum 87% Al_2O_3 free on board (f.o.b.) Chinese ports, were as follows: Shanxi, shaft, lump, $71 to $75 per ton; Shanxi rotary, lump, $85 to $90 per ton; and Guizhou, round, lump, $70 to $73 per ton. The price ranges for Guyanese refractory-grade bauxite were as follows: $155 to $175 per ton, f.o.b. barge, U.S. Gulf Coast; and $165 to $175 per ton, cost, insurance, and freight (c.i.f.) Europe.

The 2000 annual average values of U.S. imports of metallurgical-grade bauxite are listed in table 7.

The market or spot prices for alumina continued to increase during the first four months of 2000, a trend that began in April 1999, then fell dramatically through December 2000. According to Metal Bulletin, metallurgical-grade alumina spot prices on international markets began 2000 at $375 to $385 per ton. The price range increased to $420 to $440 per ton in mid-February and held steady at this range through mid-May before beginning a precipitous decline through the end of the year. By yearend, the price range had decreased to $165 to $175 per ton. Trade data released by the U.S. Census Bureau indicated that the average annual value of U.S. imports of calcined alumina was $226 per ton, free alongside ship (f.a.s.) port of shipment, and $238 per ton, c.i.f. U.S. ports.

Trade

In addition to the trade data listed in tables 8-10, various specialty aluminum compounds were also exported from and imported to the United States. The compounds exported included 7,690 t of aluminum sulfate, 19,600 t of aluminum chloride, 9,020 t of aluminum oxide abrasives, and 5,550 t of various fluoride-based compounds of aluminum, including synthetic cryolite and aluminum fluoride. The compounds imported included 23,500 t of aluminum sulfate, 1,700 t of aluminum chloride, 120,000 t of aluminum oxide abrasives, and 21,500 t of various fluoride-based aluminum compounds.

World Review

In 2000, world production of bauxite increased 6% compared with that of 1999 (table 11). Mine production was reported in 22 countries, and total world production amounted to more than 135 Mt. The largest producers of bauxite, in decreasing order of tonnage mined, continued to be Australia, Guinea, Brazil, and Jamaica, accounting for about 70% of total world production.

World output of alumina increased 5% in 2000 compared with that of 1999 (table 12). The four principal producing countries, in order of quantity of alumina produced, were Australia, the United States, China, and Jamaica. These countries accounted for almost 60% of the world's production; Australia alone accounted for about one-third.

Australia.—Comalco Ltd. selected Gladstone in Queensland as the site for its proposed new $850 million ($1.4 billion Australian) alumina refinery. The company will conduct a final feasibility study to evaluate the project's long-term viability including commercial, technical, and environmental aspects (Comalco Ltd., 2000).

Comalco and its partners in Queensland Alumina Ltd. [Comalco (30.3%), Kaiser (28.3%), Alcan (21.4%), and Pechiney (20%)] also were examining prospects for an expansion of their existing Gladstone refinery, which is the

Digitized by Google

world's largest alumina refinery with 3.74-Mt/yr capacity. With the acquisition of the remaining publicly held shares (27.6%) of Comalco, Rio Tinto plc became the company's sole owner during the first half of 2000 (Rio Tinto plc, 2001, p. 39).

Alcan acquired the remaining 30% of the Gove alumina refinery and related bauxite mine making it the sole owner of these assets. Annual capacity of the Gove refinery, located in the Northern Territory, was 1.8 Mt (Alcan Aluminium Ltd., 2001a).

Worsley Alumina Pty Ltd. completed the $1 billion expansion of its alumina refinery south of Perth. The expansion, which included the construction of a $45 million gas-fired cogeneration plant to meet the refinery's higher steam and electricity requirements, increased alumina production capacity to 3.1 Mt from 1.22 Mt (Hagopian, 2000; Metal Bulletin, 2000l).

Alcoa and Billiton plc reached an agreement whereby Billiton would acquire Reynolds Australia Alumina, Ltd. LLC, which held a 56% interest in the Worsley alumina refinery, Western Australia, for $1.49 billion. Alcoa had acquired the stake in Worsley as part of its acquisition of Reynolds Metals, and was required to sell the Worsley interest as a condition of U.S. and European antitrust approval of the Reynolds Metals acquisition (Alcoa Inc., 2000c). The sale was completed in January 2001. As a result, Billiton increased its share of Worsley to 86% and the remaining 14% was owned by Kobe Steel Ltd., Nissho Iwai Corp., and Itochu Corp. (Alcoa Inc., 2001).

Azerbaijan.—The Government of Azerbaijan united three state-owned plants—the Sumgait aluminium smelter, the Gyandzha alumina plant, and Alunite Ore Mining Co.—into a single holding company, Azeraluminy JSC. The Government then invited tenders for a management contract for these plants (Metal Bulletin, 2000c). Fondel Metal Participants, a Dutch company, won a tender for the long-term management of Azeraluminy. Fondel reportedly agreed to invest $1 billion in the company and to modernize and expand production capacity at the 50,000-t/yr Sumgait smelter, the 450,000-t/yr Gyandzha refinery, and a bauxite mine (CRU Alumina Monitor, 2000).

Brazil.—Construction work on an 800,000-t/yr expansion has begun at the Alumina do Norte do Brazil S.A. (Alunorte) 1.5-Mt/yr alumina refinery. Brazil's National Development Bank would finance 70% of the cost, and the partners in Alunorte with the exception of the Japanese Consortium would finance the remainder. The remaining partners were Norsk Hydro ASA (25.25%), Mineração Rio do Norte (MRN) (12.62%), and Cia. Brasileira de Aluminio (CBA) (3.62%). Production was expected to begin at the end of 2002 and full production from the expansion would be available by mid-2003 (Mining Journal, 2000a).

The equity partners in MRN's Trombetas bauxite mine approved an expansion that would increase production by about 50% to 16.3 Mt/yr from 11 Mt/yr by 2003 (Alcan Aluminium Ltd., 2001b, p. 31). Alumina refinery expansions will require an increase in bauxite feed material, and this mine expansion should help to meet the increased demand. MRN's shareholders are Companhia Vale do Rio Doce (40%), Alcoa (13.12%), Billiton (12.5%), Alcan (12.5%), CBA (12.5%), Norsk Hydro (5%), and Abalco SA (4.37%) (Metal Bulletin, 2000d).

China.—Company officials reported that Pingguo Aluminium Co. had completed all of the financing and was awaiting final Government approval to start its phase 2 alumina expansion. The project would increase Pingguo's refinery production capacity to about 800,000 t/yr from 350,000 t/yr. The project was expected to take 3 years to complete, after which an additional expansion to 1.25 Mt/yr is planned (Platt's Metals Week, 2000b).

Guinea.—Russia's Sibirsky Aluminy (now part of Russky Aluminy) signed an agreement with the State Bauxite Co. of Guinea for a long-term supply of bauxite. Under the agreement, Guinea will supply bauxite to Sibirsky's alumina refineries in Russia and the Ukraine in exchange for mining equipment (Metal Bulletin, 2000k).

Hungary.—Magyar Aluminium Rt (MAL) integrated its 100%-owned affiliates (Ajkai Timfold Kft, owner of the 280,000-t/yr Ajka alumina refinery, and Inotai Aluminium Kft, owner of the 35,000-t/yr Inota aluminum smelter) into one holding company to reduce administrative costs and to simplify strategic planning (CRU Aluminium Monitor, 2000).

India.—Alcan sold its 54.6% stake in Indian Aluminium Co. Ltd. (Indal) to Hindalco Industries Ltd. Included in the sale was Alcan's share of production from Indal's 90,000-t/yr refinery at Muri and the 250,000-t/yr refinery at Belgaum (Metal Bulletin, 2000a).

National Aluminium Co. Ltd. (Nalco) completed the first phase of its alumina expansion program. Debottlenecking at its 800,000-t/yr Damanjodi refinery increased capacity to 1.05 Mt/yr of alumina. The company planned to further expand capacity to 1.575 Mt/yr in 2001. In addition, production capacity at Nalco's open pit bauxite mine on the Panchpatmali hills of the Koraput District in Orissa was doubled to 4.8 Mt/yr from 2.4 Mt/yr (National Aluminium Co. Ltd., Operations, accessed August 3, 2001, at URL http://nalcoindia.com/invdefault.htm).

Kazakhstan.—Kazakhstan Mineral Resources Group announced plans to increase production capacity at its 1.2 Mt/yr Pavlodar alumina refinery to 1.5 Mt/yr by 2005. The company expected to steadily increase the annual production levels by technological upgrades and the installation of new equipment without changing the existing process (Metal Bulletin, 2000e).

Romania.—Russky Aluminy (Russian Aluminium), which took control of operations at the Oradea refinery, restarted the plant using imported Australian bauxite. Russian Aluminium expected to continue to increase production during 2001 and to reach production capacity of 250,000 t/yr in 2002. In later years, annual capacity at the refinery may be increased to 300,000 to 350,000 t/yr (Metal Bulletin, 2000h).

Russia.—A new aluminum company, Russky Aluminy (Russian Aluminium), was formed by combining the assets of the Sibneft shareholder group and Siberian Aluminium. Russian Aluminium manages about 70% of Russia's primary aluminum smelting capacity. The company controls Russia's three largest smelters—Bratsk (900,000 t/yr), Krasnoyarsk (800,000 t/yr), and Sayansk (400,000 t/yr). As for alumina production, the company controls the Achinsk (900,000 t/yr) and the Nikolayev (1.05 Mt/yr) refineries. The downstream operations that are either fully or partly owned by the company include the Samara Metallurgical Plant, the Sayanal foil mill, the Rostar can plant, and the Belaya Kalitva Metallurgical

Digitized by Google

Production Assn. (Metal Bulletin, 2000j).

A second new group, SUAL Holding, resulted from a merger of the aluminum assets of Siberian-Urals Aluminium Co. and the Trustconsult Group. SUAL controls the Irkutsk (262,000 t/yr), Bogoslovsk (162,000 t/yr), Uralsky (70,000 t/yr), and Kandalaksa (63,000 t/yr) primary aluminum smelters. The company also owns the Bogoslovsk (930,000 t/yr) and Uralsky (570,000 t/yr) refineries, the Northern and Southern Urals bauxite mines, and the Sredny-Timan bauxite deposits (CRU Alumina Monitor, 2000). Downstream facilities include the Kamensk-Uralsky Metallurgy Plant (rolling mill), the Mikhailovsky Nonferrous Metal Processing Plant (Mikhalum foil plant), and the Irkutsk and Kirinsky cable plants (Interfax Mining & Metals Report, 2000b).

SUAL announced plans to expand production at the Sredny-Timan deposit to 2.5 Mt/yr by 2005. An annual capacity of 6.5 Mt was planned by 2020. The mined bauxite provides raw material for the Uralsky refinery. The ore is moved by truck over an ice field during the winter, but a new rail track is under construction to provide year-round transport. The company reported that a new refinery could be built at the mine site to produce alumina for sale to other Russian producers in the future. Explored reserves at the deposit were estimated at 250 Mt (Interfax Mining & Metals Report, 2000c, d).

Russian Aluminum announced plans to invest about $6.5 million (193 million rubles) to increase production at the Achinsk alumina refinery to meet its engineered capacity of 900,000 t/yr. The first phase of the upgrade was used to buy new equipment for the plant's nepheline mines. Production in 1999 was estimated at 770,000 t. The company planned to reach full production levels in 2002 (Metal Bulletin, 2000i).

The 268,000-t/yr Pikalevo alumina refinery signed a new 5-year supply agreement with Apatit, a supplier of nepheline concentrates. Apatit resumed concentrate shipments and agreed to supply 90,000 t of concentrates per month over the life of the contract. The Pikalevo refinery supplies the Vogograd and Volklov smelters (Interfax Mining & Metals Report, 2000a).

Ukraine.—Ukrainian Aluminium Co., a subsidiary of Russian Aluminium, reported that contracts were signed for 1.6 Mt of bauxite from Brazil, Guyana, India, and Italy to supply the 1.05 Mt/yr Nikolayev alumina refinery. Additional supply contracts with Australia, Guinea, Sierra Leone, and Venezuela were also being negotiated (Metal Bulletin, 2000g).

Ukrainian Aluminium also submitted plans for expanding capacity at the Nikolayev refinery to 1.5 Mt/yr. The expansion reportedly would involve upgrading the existing facility, rather than requiring additional construction (Metal Bulletin, 2000f).

Venezuela.—Pechiney signed a contract to invest $260 million over 3 years in Bauxilum, Venezuela's state-owned bauxite and alumina producer. The upgrade program would increase capacity at the 1.7 Mt/yr alumina refinery to 2.1 Mt/yr. Pechiney would not have a direct interest in Bauxilum, but would receive its investment return in the form of the 400,000 t/yr of additional alumina production (Mining Journal, 2000b).

Outlook

Identified world bauxite reserves are sufficient to meet cumulative world demand well into the 21st century. Considering the probability of discovering additional bauxite deposits plus the added possibility of employing lower grade bauxite occurrences and various alternative sources of alumina, world resources of aluminum remain adequate to satisfy demand for the foreseeable future.

Weakness in the national economies of most areas of the world will restrict growth and possibly decrease demand for aluminum in 2001. Most forecasters, however, anticipate that this weakness will be short-lived and that demand will pick up in 2002 and thereafter. The automotive and construction industries will continue to be the major drivers for aluminum use. Overall, world demand is expected to grow, despite a possible drop in the growth rate for the next year or so as the world economies begin their recoveries.

As for aluminum metal production, energy costs and shortages continued to force companies to idle smelter capacity during the first half of 2001. Additional production from newly commissioned smelters and brownfield expansions should keep world metal supply and demand fairly balanced in 2001. However, the alumina market ended 2000 in an oversupply condition that continued during the first half of 2001. Despite increased exports of alumina by Western refiners to both the Chinese and Russian markets, this oversupply situation in the alumina market is likely to continue until aluminum metal demand and production increase.

(Thousand metric tons)

	1996	1997	1998	1999	2000
United States:					
Production, crude ore (dry equivalent)	W	NA	NA	NA	NA
Value	W	NA	NA	NA	NA
Exports (as shipped):					
Crude and dried	92	64	83	115	133
Calcined	40	21	16	34	9
Imports for consumption (as shipped):					
Crude and dried	10,200	10,700	11,000	9,890	8,550
Calcined	352	369	393	299	310
Consumption (dry equivalent)	11,000	11,500	12,700	11,700	10,600
World, production	117,000	122,000	122,000	128,000 r/	135,000 e/

e/ Estimated. r/ Revised. NA Not available. W Withheld to avoid disclosing company proprietary data.
1/ Data are rounded to no more than three significant digits.

TABLE 2
ESTIMATED PRODUCTION AND SHIPMENTS OF ALUMINA IN THE UNITED STATES 1/

(Thousand metric tons)

			Total	
Year	Calcined alumina	Other alumina 2/	As produced or shipped 3/	Calcined equivalent
Production:				
1998	5,100	820	5,920	5,650 r/
1999	4,620	780	5,400	5,140 r/
2000	4,310	691	5,000	4,780
Shipments:				
1998	5,080	822	5,910	5,640 r/
1999	4,600	780	5,380	5,130 r/
2000	4,300	691	4,990	4,770

r/ Revised.
1/ Data are rounded to no more than three significant digits.
2/ Trihydrate, activated, tabular, and other aluminas. Excludes calcium and sodium aluminates.
3/ Includes only the end product if one type of alumina was produced and used to make another type of alumina.

TABLE 3
CAPACITIES OF DOMESTIC ALUMINA PLANTS, AS OF DECEMBER 31, 2000 1/ 2/

(Thousand metric tons per year)

Company and plant	1999	2000
Alcoa Inc.:		
Point Comfort, TX	2,300	2,300
St. Croix, VI 3/	600	600
Total	2,900	2,900
BPU Reynolds, Inc., Corpus Christi, TX	1,600	1,600
Kaiser Aluminum & Chemical Corp., Gramercy, LA	(4/)	1,250 4/
Ormet Corp., Burnside, LA	600	600
Grand total	5,100	6,350

1/ Capacity may vary depending on the bauxite used.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.
3/ Temporarily shutdown.
4/ Damaged in an explosion, partial restart in December 2000.

TABLE 4
U.S. CONSUMPTION OF BAUXITE, BY INDUSTRY 1/

(Thousand metric tons, dry equivalent)

Industry	1999	2000
Abrasive	113	111
Alumina	11,100	10,100
Chemical	W	W
Refractory	251	160
Other 2/	229	225
Total	11,700	10,600

W Withheld to avoid disclosing company proprietary data; included with "Other.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes cement, municipal water works, oil, and steel and ferroalloys.

TABLE 5
STOCKS OF BAUXITE IN THE UNITED STATES, DECEMBER 31 1/ 2/

(Thousand metric tons, dry equivalent)

Sector	1999	2000
Producers, processors, consumers	1,440	1,300
Government	6,800	5,710
Total	8,250	7,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Domestic and foreign bauxite; crude, dried, calcined, activated, all grades.

TABLE 6
STOCKS OF ALUMINA IN THE UNITED STATES, DECEMBER 31 1/ 2/

(Thousand metric tons, calcined equivalent)

Sector	1999	2000
Producers	349	334
Primary aluminum plants	959 r/	950
Total	1,310 r/	1,290

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Excludes consumers stocks other than those at primary aliminum plants.

TABLE 7
AVERAGE VALUE OF U.S. IMPORTS OF CRUDE AND DRIED BAUXITE 1

(Per metric ton)

	1999		2000	
Country	Port of shipment (f.a.s.)	Delivered to U.S. ports (c.i.f.)	Port of shipment (f.a.s.)	Delivered to U.S. ports (c.i.f.)
Australia	$12.11	$20.09	$13.50	$25.53
Brazil	24.32	31.15	23.51	29.82
Guinea	22.37	28.81	23.05	29.09
Guyana	24.58	35.66	26.01	36.80
Jamaica	17.05	23.93	19.53	24.97
Weighted average	21.56	28.67	23.09	29.94

1/ Computed from quantity and value data reported to U.S. Customs Service and compiled by the U.S. Census Bureau, Department of Commerce. Not adjusted for moisture content of bauxite or differences in methods used by importers to determine value of individual shipments.

BERYLLIUM

By Larry D. Cunningham

Domestic survey data and tables were prepared by Jesse J. Inestroza, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

Beryllium (Be), silver in color and one of the lightest of all metals, has one of the highest melting points (about 1,280° C) of all light metals. It has physical and chemical properties, such as its stiffness, resistance to corrosion from acids, and electrical and thermal conductivity, that make it useful for various applications in its alloyed, oxide, and metallic forms. Only two beryllium minerals, beryl and bertrandite, are of commercial importance; beryl contains about 4% Be and bertrandite contains less than 1% Be. Bertrandite is the principal beryllium mineral mined in the United States, and beryl is the principal mineral produced in the rest of the world.

In 2000, U.S. production of beryllium ore and total ore consumption for the production of beryllium alloys, beryllium metal, and beryllium oxide continued to decrease (table 1). Beryllium was used in applications such as computers, telecommunications, and automotive electronics.

The Defense National Stockpile Center (DNSC), U.S. Department of Defense, continued to offer and sell selected beryllium materials from the national defense stockpile (NDS). The Generalized System of Preferences (GSP), a renewable preferential trade program, was extended to September 30, 2001. Most beryllium price quotations remained unchanged. Overall U.S. exports of beryllium were down and overall imports of beryllium were up in 2000 compared with those in 1999.

Legislation and Government Programs

To ensure a supply of beryllium during an emergency, various materials have been purchased for the NDS. The stockpile goal, effective as of October 5, 1999, for beryllium metal was 45 metric tons (t), (table 2). For fiscal year (FY) 2000 (October 1, 1999, through September 30, 2000), the DNSC sold about 1,810 t of beryl ore valued at about $158,000; about 2,040 t of beryllium copper master alloy (BCMA) valued at about $12 million; and about 23 t of beryllium metal valued at about $4.15 million from the NDS. As of September 30, 2000, beryllium inventory sold but not shipped from the NDS included about 3,050 t of beryl ore; about 1,110 t of BCMA; and about 29 t of beryllium metal (U.S. Department of Defense, 2001, p. 13-14, 42, 47).

In its revised annual materials plan (AMP) for FY 2001 (October 1, 2000, through September 30, 2001) and proposed AMP for FY 2002 (October 1, 2001, through September 30, 2002), the DNSC had authority to sell about 3,630 t of beryl ore, about 2,000 t of BCMA, and about 36 t of beryllium metal (Defense National Stockpile Center, 2001a, b). The National Defense Authorization Act for FY 2000 (Public Law 106-65, October 5, 1999) authorizes the President of the United States to dispose of about 227 t of beryllium metal from the NDS. The President may not, however, dispose of the material to the extent that the disposal will result in "(1) undue disruption of the usual markets of producers, processors, and consumers of the materials proposed for disposal; or (2) avoidable loss to the United States" (U.S. Department of Defense, 2001, p. 31, 32). For FY 2001, through June 30, 2001, the DNSC sold about 1,260 t of BCMA valued at about $7.62 million and about 23 t of beryllium metal valued at about $3.62 million from the NDS.

Under the GSP, the United States grants duty-free access to eligible products from designated developing countries. In

Beryllium in the 20th Century

Beryllium was discovered in 1797 as a constituent of the mineral beryl. The metallic form was isolated in 1828 and named beryllium. It was not until 1926, however, that the true value of beryllium was realized. U.S. production of beryllium-copper alloys began in 1932, and in the 1940s, a commercial process was developed to produce beryllium metal. An early use for beryllium was in copper and nickel alloys, which were used in electrical components in machinery. In 1969, a beryllium mine opened in Utah that provided a large secure source of domestic raw material supply. Although statistics are not available for beryllium in the early years of its development, in 1940, U.S. mine shipments of beryllium ore (mostly from Colorado, Maine, and South Dakota) totaled about 110 metric tons valued at about $3,720. World production of beryllium ore was about 2,100 tons; Argentina was the major producer accounting for about 70% of the total. U.S. imports of beryllium ore totaled about 730 tons valued at about $24,000; Argentina and Brazil were the major sources.

In 2000, the United States was one of three countries that processed beryllium ores and concentrates into beryllium products. World beryllium ore production totaled about 6,000 tons; the United States, Russia, and Kazakhstan were the leading producers. Beryllium ore production in the United States was about 4,500 tons, mostly from Utah. Beryllium imports in the form of beryllium alloy and compounds totaled more than 150 tons valued at about $2.5 million. There were no imports of beryllium ore. U.S. beryllium consumption totaled about 300 tons of contained beryllium valued at about $110 million. The use of beryllium (as an alloy, metal, and oxide) in electronic and electrical components and aerospace and defense applications accounted for an estimated 80% of total U.S. consumption.

Digitized by Google

2000, U.S. import duties for selected beryllium materials ranged from duty free to 8.5% ad valorem for normal-trade-relations (NTR) status and from duty free to 45% ad valorem for non-NTR status (U.S. International Trade Commission, 1999). In March, the GSP program, which expired on June 30, 1999, was renewed through September 30, 2001, retroactive to July 1, 1999, by a provision in the Ticket To Work and Work Incentives Improvement Act of 1999. The U.S. Customs Service began processing refunds due to the renewal on January 7, 2000 (U.S. Customs Service, 2000).

In December, the U.S. Department of Energy (DOE) published a notice of intent to establish the Worker Advocacy Committee. The Committee would provide DOE with advice, information, and recommendations on programs to assist workers diagnosed with work-related illnesses (including ongoing beryllium medical surveillance programs) in filing state workers' compensation claims. The Committee would "(1) provide advice to the Department of Energy on workers' compensation policy issues of concern to the Department; (2) periodically review worker advocacy program initiatives and recommendations; and, (3) provide advice on plans, priorities, and strategies to improve advocacy practices and procedures of the worker advocacy program." Committee members would be chosen from workers and union representatives, State and federal workers' compensation specialists, occupational physicians, medical and public health organizations, academic researchers, and the public at large (U.S. Department of Energy, 2000).

"The Energy Employees Occupational Illness Compensation Act of 2000, Public Law 106-398, establishes a program to provide compensation to individuals who developed illnesses as a result of their employment in nuclear weapons production-related activities and at certain federally-owned facilities in which radioactive materials were used." On December 7, 2000, the President issued Executive Order 13179 directing DOE to publish in the Federal Register (no later than January 15, 2001) a list of covered facilities. The list would cover three categories defined by the act—atomic weapons employer facilities, DOE employer facilities, and facilities owned and operated by a beryllium vendor. The initial list was published on January 17, 2001. The list was revised on June 11, 2001, and contained 43 beryllium-related facilities. The list indicated private firms that processed, produced, or provided beryllium metal for the DOE. The information was taken from a variety of historical documents, to the extent that DOE was able to identify and locate records, and the DOE welcomed comments and additional information about its beryllium vendors (Clinton, 2000; U.S. Department of Energy, 2001a, b).

Production

The U.S. Geological Survey collects beryllium data from two voluntary surveys of U.S. operations. In 2000, five respondents to the "Beryllium" and the "Mineral Concentrate and Beryllium Ore" surveys produced 100% of total domestic mine shipments presented in tables 1 and 7. A small number of unidentified producers may have shipped negligible quantities of byproduct beryl, which have not been included.

The United States, one of only three countries that process beryllium ores and concentrates into beryllium products, supplies most of the rest of the world with these products. Brush Wellman Inc., Cleveland, OH, mined bertrandite and converted ore of this mineral, along with imported beryl, into beryllium hydroxide at its operations near Delta, UT. Beryllium hydroxide was shipped to the company's plant in Elmore, OH, where it was converted into beryllium alloys, oxide, and metal. Brush Wellman also operated a plant in Reading, PA, that produced thin precision strips of beryllium-copper and other alloys and beryllium-copper rod and wire. About $2.4 million was spent on an annealing furnace to increase production capacity at the facility, with completion anticipated for the second half 2001 (Brush Engineered Materials Inc., 2001a, p. 3, 19, 2001b, p. 4).

In May 2000, Brush Wellman's shareholders approved the reorganization of its corporate and capital structure, and the company became a wholly owned subsidiary of Brush Engineered Materials Inc., a holding company headquartered in Cleveland, OH. Each share of Brush Wellman's common stock was exchanged for one share of Brush Engineered Materials' common stock. Brush Engineered Materials owned operations in Asia, the United States, and Western Europe and employed about 2,500 people. Company operations were organized into two business segments, the Metals Systems Group and the Microelectronics Group. The Metals Systems Group included Brush Wellman, the company's largest subsidiary, which produced strip and bulk products (mostly beryllium-containing alloys) and beryllium metal and beryllium-aluminum products (Brush Engineered Materials Inc., 2001a, p. 1, 7, 13-14, 18, 28, 33).

NGK Metals Corp., headquartered in Reading, PA, a subsidiary of NGK Insulators, Ltd. of Japan, produced beryllium alloy products at a plant in Sweetwater, TN. Because NGK Metals does not have facilities to process beryllium ores and concentrates, the company purchases beryllium oxide from Brush Wellman.

Environment

Because of the toxic nature of beryllium, the industry must maintain careful control over the quantity of beryllium dust and fumes in the workplace. The U.S. Environmental Protection Agency issues standards for certain hazardous air pollutants, including beryllium, under the Clean Air Act, and the Occupational Safety and Health Administration issues standards for airborne beryllium particles. To comply with these standards, plants are required to install and maintain pollution-control equipment. In beryllium-processing plants, harmful effects are prevented by maintaining clean workplaces; requiring the use of safety equipment, such as personal respirators; collecting dust, fumes, and mists at the source of deposition in dust collectors; establishing medical programs; and implementing other procedures to provide safe working conditions. Standards for exposure to beryllium were under review (Petkof, 1985, p. 80; Rossman, Preuss, and Powers, 1991, p. 278-280; Kramer, 1998, p. 107-108; Brush Engineered Materials Inc., 2001a, p. 6, 7, 19). Control of potential health hazards adds to the final cost of beryllium products.

Consumption

In 2000, domestic mine shipments and beryllium-containing ore consumption continued to trend downward. According to

Digitized by Google

its annual report, Brush Engineered Materials' worldwide sales continued at a record pace, about $564 million in 2000 compared with about $456 million in 1999. Beryllium-containing products accounted for more than 50% of total company sales. The domestic market accounted for 73% of the company's revenue compared with 70% in 1999. Telecommunications (33%) was the leading revenue market. The Metal Systems Group (which included Brush Wellman's Alloy Products and Beryllium Products business units) had revenues of about $378 million, about 67% of total revenues. Alloy Products (primarily copper-beryllium alloys) sales increased to $270 million. Yield and equipment reliability issues at the Elmore plant, however, limited the company's ability to supply total product market demand. The alloys, sold in strip and bulk form, are used in applications such as computers, telecommunications, automotive electronics, oil and gas exploration, and undersea communications. Beryllium Products sales increased to $25 million, owing to increased second half year sales of beryllium aluminum alloy and beryllium metal products for defense related applications. Company international sales totaled about $150 million ($98.4 million from international operations, with facilities in England, Germany, Japan, and Singapore, and $51.2 million from U.S. operations' exports) compared with about $138 million in 1999 (Brush Engineered Materials Inc., 2001a, p. 2-3, 6, 13-14, 16; 2001b, p. 3).

During the year, Brush Wellman entered into a long-term supply arrangement with Kazatomprom National Atomic Co. and Ulba Metallurgical Plant Open Stock Co. in Kazakhstan and their marketing representative Nukem Inc. in New York for the supply of copper-beryllium master alloy and certain other beryllium-containing materials. Brush Wellman was to purchase the alloy and materials from Nukem, a wholly owned subsidiary of Tessag AG, Germany, which had a supply agreement with Ulba, a unit of Kazatomprom, who would produce the material. Annual purchase commitments for 2001 through 2009, totaled $5.8 million in 2001, $7.7 million in 2002, $9.7 million in 2003, $11.6 million in 2004, $13.5 million in 2005, and $15.4 million per year thereafter. Also, Brush Wellman was to purchase $3 million of beryllium ingot in 2001. The agreement could be terminated at any time with written notice for causes of action. The purchased material would be used by Brush Wellman in the manufacture of high-performance alloy products and would augment its U.S. beryllium sources (Brush Wellman Inc., 2000; Brush Engineered Materials Inc., 2001a, p. 22, 40).

U.S. apparent consumption of all beryllium materials was estimated to be about 300 t of contained beryllium in 2000 compared with about 385 t in 1999.

Beryllium-Copper Alloys.—Beryllium-copper alloys, most of which contain approximately 2% beryllium, are used in a wide variety of applications. These alloys are used because of their electrical and thermal conductivity, high strength and hardness, good corrosion and fatigue resistance, and nonmagnetic properties. Beryllium-copper strip is manufactured into springs, connectors, and switches for use in applications in automobiles, aerospace, radar and telecommunications, factory automation, computers, home appliances, and instrumentation and control systems. The principal use of large-diameter beryllium-copper tubing is in oil and gas drilling equipment and in bushings and bearings in aircraft landing gear and heavy machinery. Connectors in fiber-optic telecommunications systems are the main application for beryllium-copper rod. Small, pluggable sockets for joining integrated circuits to printed circuit boards are the main application for beryllium-copper wire. Beryllium-copper bar and plate are used in resistance-welding parts, components for machinery and materials-handling systems, and for molds to make metal, glass, and plastic components.

Beryllium also is used in small quantities in nickel- and aluminum-base alloys. Miniature electronic connector components that operate at high temperatures are the main use for beryllium-nickel alloys. These alloys also are used in automotive passive restraint systems (airbags). Beryllium-aluminum alloys are used as castings in the aerospace industry. The addition of small quantities of beryllium to magnesium alloys inhibits oxidation.

Beryllium Metal.—Beryllium metal is used principally in aerospace and defense applications. Its high level of stiffness, light weight, and dimensional stability within a wide temperature range make it useful in satellite and space vehicle structures, inertial guidance systems, military aircraft brakes, and space optical system components. Because beryllium is transparent to x rays, it is used in x-ray windows. In nuclear reactors, beryllium also serves as a canning material, as a neutron moderator, and in control rods. In the past, the metal had been used as a triggering device in nuclear warheads. Other applications for metallic beryllium include high-speed computer components, audio components, and mirrors. In the U.S. space shuttles, several structural parts and brake components use beryllium.

Beryllium Oxide.—Beryllium oxide (beryllia) is an excellent heat conductor, with high levels of hardness and strength. This material also acts as an electrical insulator in some applications. Beryllium oxide serves mainly as a substrate for high-density electronic circuits for high-speed computers, automotive ignition systems, lasers, and radar electronic countermeasure systems. Because it is transparent to microwaves, microwave communications systems and microwave ovens may use beryllium oxide.

Because the cost of beryllium is high compared with that of other materials, it is used in applications in which its properties are crucial. Graphite, steel, and titanium may be substituted for beryllium metal in some applications, and phosphor bronze may be substituted for beryllium-copper alloys, but these substitutions can result in substantial loss in performance. In some applications, aluminum nitride may be substituted for beryllium oxide.

Prices

Yearend price quotes for beryllium materials and products are shown in table 3. Published prices for most beryllium materials remained unchanged throughout the year, with the exception of beryllium metal and beryllium oxide. In June the price for 99% beryllium metal powder increased to $421 per pound, beryllium vacuum-cast ingot increased to $492 per pound, and beryllium oxide increased to $100 per pound. The American Metal Market published prices for other selected beryllium products were as follows: BCMA, $160 per pound of contained beryllium, unchanged since August 1987; beryllium-copper strip, $8.90 per pound, unchanged since January 1993; and

Digitized by Google

beryllium-aluminum alloy, $260 per pound, unchanged since January 1995. The Metal Bulletin published price for beryl ore, which ranged from $75 to $80 per short ton unit of contained BeO, has remained the same since 1990.

Significant events affecting beryllium prices since 1958 include the following: 1969, bertrandite mine established in the United States providing a significant raw materials source; 1977, effects of inflation, increased energy costs, and additional costs associated with complying with air emission standards resulted in increased prices; 1979, beryllium metal price set by one producer; 1988, purchase of beryllium metal for the NDS; 1990, conversion of NDS beryl ore to beryllium metal for the NDS; and 1991, recession and dissolution of the U.S.S.R (Cunningham, 1999).

Foreign Trade

Data for U.S. exports and imports are summarized in tables 4 and 5, respectively. Overall beryllium exports were down by about 14% compared with those of 1999. France, Germany, Japan, the Republic of Korea, the Netherlands, and the United Kingdom were the major recipients of the materials, with about 85% of the total. Overall beryllium imports increased by about 20%. BCMA imports were up by more than 40%, with Germany providing more than 70% of the imports. Metal imports were down by more than 10%, with China, Estonia, and the United Kingdom accounting for about 95% of the materials. There were no beryl ore imports in 2000. The schedule of tariffs applied during 2000 to U.S. imports of selected beryllium materials is found in the U.S. International Trade Commission's Publication 3249, 2000 Harmonized Tariff Schedule of the United States (U.S. International Trade Commission, 1999).

Net import reliance as a percent of apparent consumption is used to measure the adequacy of current domestic beryllium production to meet U.S. demand. For 2000, net import reliance as a percent of apparent consumption was estimated to be about 37% compared with about 48% in 1999. In descending order, Estonia, Germany, and China were the major sources for U.S. beryllium imports, on the basis of contained beryllium, accounting for more than 80% of the total. Other sources of imports were Belgium, Russia, and the United Kingdom.

The U.S. Census Bureau does not separately identify all imports and exports of beryllium products. The Journal of Commerce Port Import/Export Reporting Service (PIERS) provides some data on materials that are transported by ship. According to PIERS, about 890 t, gross weight, of beryllium products (mostly beryllium-copper) was imported in 2000, primarily from Japan. Exports of beryllium products (mostly beryllium-copper) totaled more than 600 t, gross weight; Japan received most of this material.

World Review

Annual world beryl production capacity (metric tons, contained beryllium) is listed in table 6. Estimated world beryl production (metric tons, gross weight) is listed in table 7. In 2000, estimated world beryl production (including bertrandite ore) decreased by about 9% compared with that of 1999. The two major producers, Russia and the United States, accounted for about 97% of total production.

Japan.—In November 1999, NGK Insulators completed a 2-year investment program that increased beryllium-copper alloy capacity at its plant in Handa, near Nagoya, to about 350 metric tons per month (t/mo) from about 300 t/mo. NGK indicated that Japanese and Asian demand for beryllium-copper alloys in 1999 was about 3,500 t. In addition to regional sales, NGK shipped semifinished products from Handa to its subsidiaries in Germany and the United States for fabrication. In 2000, Japanese demand for beryllium-copper alloys increased to a record level of about 300 t/mo, owing to increased use in portable telephones and automotive electrical equipment (Roskill's Letter from Japan, 2000; Metal Bulletin, 2001).

Kazakhstan.—Kazatomprom, Kazakhstan's national nuclear concern, reportedly invested about $36 million to develop beryllium, tantalum, and uranium production. Projects conducted included the introduction of carbothermy technology and the production of beryllium bars at the Ulba Metallurgical Plant. Kazatomprom owns 90% of Ulba shares. Kazatomprom's contract to supply Brush Wellman with beryllium, and for the exchange of technology, was reported to be worth more than $120 million (see consumption section of this report) (Interfax International Ltd., 2000a, b).

Russia.—At yearend 1999, the Chita region made a decision to join a federal program named Libton for the creation of a scientific production center for rare metals, including beryllium, in the Trans-Baikal region. The Chita region and TVEL, a producer and supplier of nuclear fuel controlled by the Russian Ministry of Atomic Energy, signed an agreement on liaison with the Priargunsky Mining and Chemicals Production Association, a uranium producer controlled by TVEL, and the Zabaikalsky Mining and Beneficiation Plant, a rare metal producer. The Ministry was to finance the program and coordinate efforts by Priargunsky and Zabaikalsky to produce materials for the nuclear sector (Interfax International, Ltd., 2000c).

Outlook

Beryllium alloys, primarily beryllium-copper, are expected to remain the dominant form of consumption for beryllium. Beryllium demand should rise owing to increased usage of beryllium-copper in automotive electronics, computers, and portable telephones. Also, the newer beryllium-aluminum alloys are expected to gain in importance in terms of beryllium demand, with usage in applications such as aerospace and computers. The beryllium-aluminum alloys contain up to about 60% beryllium, compared with beryllium-copper alloys, most of which contain about 2% beryllium (American Metal Market, 2000; Harben, 2000, p. 13, 14; Mining Journal, 2000).

The United States is expected to remain self-sufficient with respect to most of its beryllium requirements. In 2000, the United States consumed about 240 t of beryllium contained in beryllium-bearing ores, compared with about 260 t in 1999. Brush Engineered Materials Inc. (2001a, p. 20) reported proven bertrandite reserves in Juab County, UT, of about 7 million metric tons at yearend 2000, with an average grade of 0.263% beryllium. This represents about 18,300 t of contained beryllium, compared with about 18,700 t in 1999. About 87% of the beryllium is recovered from the ore during the extraction process.

BISMUTH

By Robert D. Brown, Jr.

Domestic survey data and tables were prepared by Carolyn F. Crews, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

U.S. bismuth consumption increased 4% during 2000, compared with that of 1999. Consumption increased in all sectors: bismuth alloys, chemicals and pharmaceuticals, and metallurgical additives. In 2000, all primary bismuth consumed in the United States was imported. The only domestic refinery, in Nebraska, produced bismuth as a byproduct of lead refining until July 1997. The last stocks of bismuth held in the national defense stockpile (NDS) were sold that same year. The largest foreign producers of refined bismuth were Belgium, China, Mexico, and Peru.

Domestically, about 42% of bismuth was used in bismuth alloys, 40% in pharmaceuticals and chemicals, 16.5% as metallurgical additives, and 1.5% for other uses (table 2). Only a small amount of bismuth was obtained by recycling old scrap.

In recent years, several new uses for bismuth have been developed as nontoxic substitutes for lead in various applications. These included the use of bismuth in brass plumbing fixtures, ceramic glazes, crystalware, fishing sinkers, lubricating greases, pigments, and solders. Bismuth was a leading candidate for replacing lead in applications that have an environmental impact, such as shot used for waterfowl hunting. Another newly developed use was in galvanizing to improve drainage of galvanizing alloys. Poor drainage causes galvanizing alloy to accumulate in corners and angles as well as bridge small holes and thin channels, which requires extra cleaning of the workpiece. Lead additions improve the drainage properties of galvanizing alloys. Zinc-bismuth alloys have the same drainage properties as zinc-lead alloys without the toxicity of lead (Gagné, 2000).

In 2000, the average New York dealer price for bismuth decreased from $3.85 per pound to $3.70 per pound (table 1). This reversed increases in 1998 and 1999, but the average price was still the second highest in 5 years. The value of bismuth consumed domestically in 2000 was about $17.4 million, the same as for 1999.

Legislation and Government Programs

The Defense Logistics Agency, which administers the NDS, sold the final 85 metric tons (t) of bismuth in the stockpile on November 4, 1997.

The conversion to plumbing alloys that contain bismuth rather than lead is driven by the Safe Drinking Water Act Amendments of 1996 (Public Law 104-182). This law bans lead from all fixtures, fluxes, pipes, and solders used for the installation or repair of facilities providing water for human consumption after August 1998.

The U.S. Environmental Protection Agency announced new standards for dangerous levels of lead on painted indoor surfaces, in dust, and on bare soil where children play. These new standards will provide new and uniform benchmarks on which to base remedial action to be taken to safeguard the public from exposure to lead. The standards, which affect Federal agencies, and State, local, and tribal governments, could further the use of bismuth as a lead substitute (U.S. Environmental Protection Agency, 2000).

The Copper Development Association has changed the name of its alloys, introduced in 1995 as SeBiLOY (containing selenium and bismuth), to Envirobrass to highlight the significant environmental and health benefits of the alloys to manufacturers and consumers. Envirobrass I and II contain a mixture of bismuth and selenium substituted for lead in red

Bismuth in the 20th Century

In 1900, the United States produced 200 metric tons of bismuth ore, all mined in Colorado, primarily bismuth carbonate from Lake County. The ore averaged about 7% bismuth and had a value of about $9 per ton, based on bismuth content. The ore also contained gold and silver, increasing its price to $70 per ton. The world's supply and pricing of metallic bismuth were closely controlled by Johnson Matthey and Co., Ltd., of England and the Government of Saxony, which today is a State of Germany. Supply was much greater than demand. Imports of bismuth totaled 82 tons valued at $250,000. A small amount of bismuth was imported in medical preparations. The main use for bismuth was in the manufacture of low-melting-point alloys for electric fuses, safety plugs for steam boilers, solders, amalgams, and baths for steel tempering. Most of these alloys contained various combinations of lead, tin, and cadmium with bismuth. In 1906, the Betts process for refining lead bullion became the major source of bismuth; since then bismuth has been known as a byproduct metal.

In 2000, U.S. consumption of bismuth was more than 2,000 tons; bismuth alloy consumption was 890 tons, chemical and pharmaceutical uses accounted for 860 tons, and metallurgical additives plus other uses reached approximately 380 tons. New uses included replacement for lead associated with environment or public health concerns (such as in fishing sinkers, waterfowl shot, and plumbing fixtures), weather resistant paints, and hot dip galvanizing. Since 1997, when domestic production and national stockpile sales ended, the United States has been completely dependent on imports for primary bismuth; only a relatively small amount of bismuth is recycled in the country. The world's leaders in refinery production in 2000 were Belgium, China, Mexico, and Peru. Although a myriad of new uses increased world bismuth demand during the 20th century, adequate reserves indicated that supply would be sufficient for future needs.

Digitized by Google

brasses used for water meters, valves, and plumbing fixtures. A new alloy, Envirobrass III, is a lead-free yellow brass for permanent mold casting (Payne, 2000).

The Danish Minister for Environment and Energy announced that the country would prohibit lead in several products where it can be replaced. The ban takes effect in 2001 and has the goal of reducing lead consumption by one-third in the next few years (Mining Journal, 2000a).

Production

ASARCO Inc., formerly the only U.S. producer of primary bismuth, ceased production on June 30, 1997. Some domestic firms continued to recover secondary bismuth from fusible alloy scrap in 2000, but secondary production data were not available. Secondary production was estimated to be no more than 5% of domestic supply during the year.

Consumption

Domestic bismuth consumption data are collected by the U.S. Geological Survey through a voluntary survey. Of the 40 firms that received the consumption survey in 2000, 70% responded. The respondents accounted for an estimated 75% of the bismuth consumption in the United States. The amount used by the nonrespondents was estimated on the basis of reports from prior years or information from other sources.

Bismuth consumption in 2000 was estimated to be 2,130 t, a 4% increase from that of 1999 (table 1). There were small or moderate increases in each sector: bismuth alloys, chemical and pharmaceutical uses, and metallurgical additives in 2000. Chemical uses, comprising most of the bismuth consumed in earlier years, accounted for less than one-half of the bismuth used domestically for the fourth successive year; in 2000, it was supplanted for the first time as the leading sector of consumption. The best known chemical use is that of bismuth subsalicylate, the active ingredient in over-the-counter stomach remedies. Other bismuth pharmaceuticals are used to treat burns, intestinal disorders, and stomach ulcers; veterinary applications are important as well. Bismuth nitrate is the initial material used for the production of most other bismuth compounds. Other bismuth chemical and compound uses include applications ranging from superconductors to some pearlescent pigments in cosmetics and paints.

Bismuth metal is used primarily as an alloy and metallurgical additive (table 2). One class of bismuth alloys comprises the fusible (low-melting-point) alloys—combinations of bismuth and other metals, such as cadmium, gallium, indium, lead, and tin. Applications for these alloys included fuel tank safety plugs, holders for lens grinding and other articles for machining or grinding, solders, and sprinkler triggering mechanisms. Also, the metal used to produce shot for waterfowl hunting is categorized as a bismuth alloy.

Bismuth is added in small amounts to aluminum, copper, and steel alloys to improve machinability. It is also added to malleable iron to prevent the formation of graphite flakes.

There remains considerable interest in using bismuth as a nontoxic substitute for lead in several applications. Bismuth oxide has been replacing lead oxide in the fire assaying of precious metals and in ceramic glazes, and bismuth replaces lead as well as steel in shotgun pellets. In fact, one area of steady increase since 1994 has been the use of bismuth alloy cartridges for waterfowl hunting; the alloy has been 97% bismuth and 3% tin.

Bismuth also has been the primary candidate of researchers seeking substitutes to replace lead in products that traditionally have contained lead, such as plumbing fixtures and solders. Alloys that use bismuth (often in combination with selenium) to replace lead in plumbing brasses are in regular production. This strategy appears to be a promising metallurgical approach to meeting more stringent tapwater standards in the United States. Although bismuth use in water meters in particular has increased, growth in bismuth consumption as a metallurgical additive remained somewhat sluggish in 2000.

There has been an effort to replace lead in other applications as well. For example, bismuth has been a substitute for the lead added to steel to provide greater machinability. A major domestic steel company began to use a bismuth-containing substitute for the leaded alloy nearly 20 years ago. Nevertheless, although bismuth has been successful in replacing lead in various applications, it has been challenged as a lead substitute by tungsten and tin (Cusack, 1999).

Prices

The domestic dealer price for commercially pure bismuth, published by Platt's Metals Week, averaged about $3.70 per pound in 2000, representing a 4% ($0.15) decrease after 4% and 3% increases in 1999 and 1998, respectively (table 1). The price was $4.30 per pound at the beginning of 2000, after fluctuating between $3.15 and $4.65 during 1999. The price fell steadily (except for one increase in March) for almost three quarters during 2000, falling to $3.23 per pound in September. Then it began a fairly rapid increase, reaching $4.00 per pound and holding there until the end of the year. In recent years, bismuth price has cycled between lows of around $3.00 per pound and highs of about $4.00 per pound (Mining Journal, 2000c); this remained true for the year 2000. A major underlying factor for the apparent $4.00 ceiling continued to be the large amount of bismuth normally available from China at lower prices (Mining Journal, 2000d). The long decline during most of the year was attributed to the resumption of supply from Mexico, and the rapid increase in the last quarter was attributed to a brief reduction of supplies from China (Ryans Notes, 2000).

Trade

Total bismuth imports increased significantly—15% by weight in 2000 (table 4). The large increase in the amount received from Mexico (86%) represents a return to normal; in 1999, bismuth production in Mexico was limited by pollution concerns.

Exports nearly doubled by weight and more than doubled by value in 2000 (table 3). The largest increases were to Germany, Mexico, and the United Kingdom.

World Review

World refinery production increased, easing concerns over supply and contributing to the downturn in prices (table 5). Production remained relatively low in Peru owing to continued use of high silver and gold concentrates in favor of high bismuth-bearing concentrates (Mining Journal, 2001).

Digitized by Google

On February 28, 2000, the Mexican environmental authority lifted restrictions on production by Industrias Peñoles, S.A., that had been affected to decrease lead pollution. This returned nearly 600 t of metal to the world bismuth market (Metal Bulletin, 2000).

Usually, bismuth is recovered as a byproduct of lead or tungsten production. The world's only significant potential source where bismuth could be the principal product is the Tasna Mine in Bolivia, which was closed in 1985 and is now for sale (Doorn, 2000). Corriente Resources Inc. of Vancouver and the state mining corporation Corporación Minera de Bolivia had planned to reopen the mine, but low prices delayed the startup. Possible byproducts or coproducts available from Tasna include copper, gold, and tungsten (Mining Journal, 1999).

Bismuth is to be a major coproduct from the new NICO Mine of Fortune Minerals, Ltd., in Northwest Territories, Canada. The deposit also contains cobalt, copper, and gold (Fortune Minerals, 2000).

In Bolivia, the newly private Vinto tin smelter was reopened by Allied Deals Corp. of the United Kingdom. In addition to tin, the smelter has a capacity of 30 tons per year (t/yr) of bismuth (Mining Journal, 2000b).

A new smelting unit at the Hunan Shizhuyuan Non-Ferrous Metal Mine, China's largest bismuth producer, was expected to increase bismuth production from 350 t/yr to more than 400 t/yr (American Metal Market, 2000). Almost 500 t, however, was produced by yearend (Metal Bulletin, 2001).

Current Research and Technology

The use of bismuth oxide additions in electronic ceramics increased, especially in Japan. The additions enhance the electronic properties of ferrites and ceramic capacitors (Roskill's Letter from Japan, 2001).

In applications such as thermal fuses and soldering, bismuth alloy wires as small as 1 millimeter in diameter are needed. A unique process is used to produce these wires. In traditional ingot casting or cold mold continuous casting, solid metal makes contact with the mold over a considerable area. The resulting friction between mold and wire causes the solidification structure normally expected: a structure that is very brittle bismuth in spite of its softness. By using a heated mold at just above the solidification temperature of the alloy, the wire is not solid until it begins to exit the mold. This can result in extremely ductile wires, which are very useful in the applications mentioned (Soda and others, 2000).

More than 100,000 t of steel have been successfully galvanized using a new galvanizing-alloy-containing bismuth. This alloy is the conventional zinc-nickel alloy used for reactive steels with the addition of 1.8% tin and 0.5% bismuth without special processing adjustments. The higher fluidity and wetability of the new galvanizing alloy results in lower consumption of zinc, better surface appearance, less dross, and less finishing required after galvanizing. A bonus is that the bath is maintained about 100° C lower than the conventional bath, resulting in a 2% reduction in energy consumption. Traditionally, lead additions have been used in many plants to produce similar results as well as to obtain a large grain size in the coating. The new procedure, however, yields as good or better results with a lead-free process (Beguin and others, 2000). A new zinc-bismuth alloy can replace the equivalent leaded alloy with good resulting properties. There is greater fluidity and better drainage of zinc (Gagné, 2000). This alloy, without nickel, is used for ordinary steels.

Yellow bismuth vanadate is a major component of a yellow pigment blend for hot-melt road markings and paints. The resulting markings have very good heat resistance, do not fade, and meet applicable transportation regulations for color and reflectance. Traditional paints for this purpose use lead and hexavalent chromium pigments. Both of these are toxic to plants and animals. The new blend is lead- and chrome-free and thus is free from environmental regulation (Gooding and Delaney, 2000).

Outlook

The long-range outlook for bismuth indicates that demand will probably grow, especially in new applications and as the development of nontoxic bismuth substitutes for lead continues. The use of bismuth in plumbing fixtures and shot for ammunition is still increasing in the United States and in Europe. A partial ban on lead has been announced in Denmark. In Japan and elsewhere, however, the increase in substitution for lead has been slow because the applicable environmental regulations are less stringent (Roskill's Letter from Japan, 1999).

Bismuth is usually a byproduct of lead; a significant near term increase in supply, therefore, is unlikely, especially because total world production of lead will remain relatively stable with a large and increasing fraction of lead demand satisfied by recycling. Nevertheless, a global shortage of bismuth is not anticipated. Despite any increase in world demand, Chinese supplies can be expected to help keep the bismuth market stable (Mining Journal, 2001).

It appears that low prices, due to the nearly constant availability of Chinese bismuth or to the general deflationary trend for metals during the past decade, are the limiting factor to bismuth supply (Carnak, 1999). Usually, more bismuth appears in the market whenever prices increase.

BORON

By Phyllis A. Lyday

Domestic survey data and tables were prepared by Christopher H. Lindsay, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Boron produced domestically during 2000 totaled 546,000 metric tons (t) of boron oxide valued at $557 million (table 1). The most common minerals of commercial importance in the United States were colemanite, kernite, tincal, and ulexite (table 2). Boron compounds and minerals sold were produced by surface and underground mining, in situ, and from brine. U.S. consumption of minerals and compounds amounted to 360,000 t of boron oxide (table 3). Boron products are priced and sold based on the boron oxide content, which varies by ore and compound, and on the absence or presence of sodium and calcium (table 4). Boron exports totaled 532,000 t (table 5). Boron imports consisted primarily of borax, boric acid, colemanite, and ulexite (tables 1, 6). The United States and Turkey were the world's largest producers of boron (table 7).

The glass industry, which remained the largest domestic market for boron production in 2000, accounted for 76% of boron consumption. Insulation-grade glass fibers accounted for an estimated 47% of domestic consumption; textile-grade glass fibers, 18%; boron sold to distributors, 9%; borosilicate glasses, 7%; soaps and detergents, 7%; enamels, frits, and glazes, 4%; and other uses, 8%.

Legislation and Government Programs

The U.S. Department of Energy (DOE) plans to store spent natural fuel encased in a boron-containing glass inside stainless steel containers underground at Yucca Mountain, NV, beginning in 2009. As a result of the DOE's delay in building a facility to accept spent nuclear fuel, PECO Energy Co. and the DOE had an agreement to reimburse costs incurred as a result of the delay. The DOE was required by law to begin accepting spent fuel by January 31, 1998 (Chemical & Engineering News, 2000a).

The U.S. Department of Justice, acting on behalf of the DOE, appealed to the district court in Las Vegas, NV, to overturn the Nevada State engineer's decision to deny water permits requested for the DOE's Yucca Mountain high-level nuclear waste project. In February, the Nevada State engineer denied the DOE's application to appropriate 530,000 cubic meters per year of water for use by the Yucca Mountain project beginning in 2002. These five permit applications for water rights were submitted by DOE in 1997 to perform activities mandated by the Nuclear Waste Policy Act (Mining Engineering, 2000a).

In 1990, the desert tortoise was listed by the Fish and Wildlife Service, U.S. Department of the Interior, as threatened. The tortoise is a major environmental issue in the Sonoran Desert, which extends from Utah to Mexico. The tortoise's habitat also includes boron areas being surface-mined and solution-mined. Since 1993, U.S. Borax Inc. has purchased and transferred more than 4,047 hectares (10,000 acres) of tortoise habitat to the Federal and State Governments at a cost of more than $5

Boron in the 20th Century

Production of borates began in California in 1864 in Lake County and in Death Valley and Armagosa Valley in 1882. In 1901, production was reported in California, Nevada, and Oregon as 16,227 metric tons of borax valued at $314,811 and 4,848 tons of refined borax valued at $697,307 for a total value of $1 million. Historical uses have included detergents, fire retardants, fluxes in glass and metals, and food preservatives. The major producing company was a California company, Pacific Coast Borax Company, which was consolidated under Borax Consolidated Ltd. (London) in 1903. In 1907, colemanite was mined in Inyo, Los Angeles, and Ventura Counties, CA. In 1914, the California borax company was liquidated, and a new Pacific Coast Borax Company was formed under Nevada law. Production from brine at Seales Lake, CA, began in 1919. Total production in 1920 was reported to be 109,153 tons valued at $2.2 million.

In 1927, large scale production of sodium borates began by Pacific Coast Borax from underground mines in Boron, CA. U.S. production in 1930 was 177,360 tons valued at $5.4 million. In 1956, the U.S. assets of Borax Consolidated were transferred to Pacific Coast Borax. In 1957, the existing three underground mines became one large surface mine. By 1960, U.S. production was reported to be 581,053 tons valued at $47.6 million, all from California.

In 1968, London-based RTZ Corp., the world's largest mining company and owner of Borax Consolidated and Pacific Coast Borax, merged with U.S. Borax. By 1970, U.S. production in California was 907,185 tons valued at $86.8 million from brines and underground and surface mines. American Borate Co., a wholly owned subsidiary of Owens-Corning, purchased the holding of Tenneco, Inc., in 1976, and development of the Billie Mine was completed in California in 1981. American Borate Co. was sold to a private firm in 1992. Mountain States Mineral Enterprises Inc. began an in situ pilot project near Newberry Spring, CA, which was sold to Fort Cady Minerals Corp., and production started at Fort Cady in 1995. Production at Searles Lake began in 1919 and continued into 2000.

In 2000, total borate production from four producers in California was reported to be 1.1 million metric tons valued at $557 million. Uses included glass (76%), sales to distributors (9%), soaps (7%), and other (8%).

Digitized by Google

million. The company also created an endowment of nearly $240,000 for the California Department of Fish and Game to maintain and enhance the tortoise habitat (Rio Tinto Borax, 2001). During the past 10 years, as many as four tortoises each year are killed at Fort Irwin, CA, at the Army training center's grounds (Washington Times, 2000).

The Federal Railroad Administration of the U.S. Department of Transportation solicited proposals for the construction of a magnetic levitation (maglev) train to be built with funds approved by the Transportation Equity Act for the 21st Century. Maglev is an advanced transportation technology in which magnetic forces lift, propel, and guide a vehicle over a specially designed guide way. Boron is used in the superconducting and other high-intensity magnets in this system. By using state-of-the-art electric power and control systems, maglev would reduce the need for many mechanical parts, thereby minimizing resistance and permitting excellent acceleration and cruising speeds of about 386 kilometers per hour (240 miles per hour) or more. Since passage of the High-Speed Ground Transportation Act of 1965, a number of maglev system concepts had undergone research and development in the United States. The Federal Government had appropriated $1 billion to explore and construct a maglev segment of rail in various locations in the United States. The Federal Government declared the Pittsburgh and the Baltimore-Washington areas the finalists in a nationwide competition to build what could be the first commercial high-speed magnetic levitation train in the world (Federal Railroad Administration, January 18, 2001, U.S. Secretary of Transportation Slater selects two high speed maglev projects, accessed June 14, 2001, at URL http://www.fra.dot.gov/o/hsgt/hot.htm).

Production

Domestic data for boron were derived by the U.S. Geological Survey from a voluntary survey of U.S. operations. The majority of boron production continued to be from Kern County, CA, with the balance from San Bernardino and Inyo Counties, CA. Of the four operations to which a survey request was sent, all responded, representing 100% of the total boron produced (tables 1, 3).

More than 200 minerals contain boric oxide, but only a few were of commercial significance (table 2). Four minerals comprised almost 90% of the borates used by industry: the sodium borates borax and kernite, the calcium borate colemanite, and the sodium-calcium borate ulexite. These minerals were extracted primarily in California and Turkey and to a lesser extent in Argentina, Bolivia, Chile, China, and Peru.

American Borate Co. mined small amounts of colemanite and ulexite-probertite from the Billie Mine in Death Valley, CA. The ore was transported to Lathrop Well, NV, for processing. Storage and grinding facilities were at Dunn, CA. Reported employment was 110 employees (Business.com, [undated], American Borate Co., accessed June 12, 2001, via URL http://www.business.com).

Fort Cady Minerals Corp. used an in situ process near Hector, CA, to produce a product containing 48% boron oxide. Because it is chemically precipitated, this product has advantages in the consistency of its chemical composition, namely, high boron oxide content, low impurities, and a consistent physical size. The product contained 25% calcium oxide, 0.8% sulfur, 0.1% chloride, 0.08% iron, and less than 1 part per million arsenic. In situ extraction required that wells be drilled 427 meters (m) (1,400 feet) into the ore body. A solution of dilute sulfuric acid was injected into wells in the borate ore. The boron-enriched solution was pumped to the surface and then reacted with lime to precipitate a pure calcium borate product. The product was dried and packaged.

In 2000, IMC Global Inc. announced the opening of new corporate headquarters in Lake Forest, IL. IMC Chemicals, headquartered in Overland Park, KS, operated the Trona and the Westend plants at Searles Lake in San Bernardino County. IMC Chemicals produced refined sodium borate and boric acid as a coproduct of soda ash and sodium sulfate from the mineral-rich lake brines. A series of closed systems circulated brines in the upper unit salt layer of the lake to increase the borax grade to a theoretical 1.45%. The brine was processed at the Westend plant and circulated back to the upper salt layer. IMC Global continued to divest a controlling share of IMC Chemicals, and another group of investors were considering purchasing the Searles Valley facilities at yearend.

U.S. Borax Inc., which was a member of Rio Tinto Borax Group, mined borate ores at Boron, CA, by open pit methods and transported the ores to the surface via a conveyor. At Boron, reserves containing the minerals kernite and tincal were reportedly in excess of 100 million metric tons (Mt) (Baele, 2000). Production was reported to be 570,000 t during 2000 compared with 543,000 t in 1999 (Rio Tinto, 2000). The stripping ratio was more than 36:1, and the quality of stripped overburden was projected to reach 100 Mt in 2000. During 2000, it was necessary to remove a layer of overburden between 107 m and 198 m thick to access the ore. As the mine advanced to the east and southeast, that overburden layer was projected to gradually increase to 366 m in thickness. A 32 t groundslide on the north slope of the pit in 1999 was the initiative for construction of less steep benches, starting at the top of the existing 17 benches. The 91-m thick ore contains four zones. The upper layer is borax, overlaying three layers of borax and kernite (Garrett, 2000). Ore was processed into sodium borate or boric acid products in the refinery complex adjacent to the mine. An onsite plant also produced anhydrous sodium borate and boric oxide. Refinery products were shipped by railcar or truck to North American customers or to the U.S. Borax Wilmington, CA, facility at the port of Los Angeles for international distribution. California employees include 1,100 people working at the principal mine and refinery in Boron, a refinery and shipping terminal in Wilmington, the global headquarters in Valencia, and a trona mine at Owens Lake that supplies raw material to the Boron refinery (Rio Tinto Borax, 2001).

Cogeneration plants, which are part of the boron-processing facilities at Boron, produced 100 megawatts (MW) of electricity, 85 MW of which were sold to Southern California Edison. One-third of the electricity used at the site goes to operate pollution control equipment (Rio Tinto Borax, 2001). Another cost saving practice was a daily tire pressure check, which would increase tire life by 40%. An environmentally sound practice blended engine oil with diesel fuel to dispose oil and increase engine life by 20% (Garrett, 2000).

A new $10 million plant at Boron was projected to be able to process more than 1,400 metric tons per day of dry pond material containing 300,000 metric tons per year (t/yr) of high

Digitized by Google

quality feed (25% boron oxide) for the sodium borate process. Before 1985, thickened clays and muds were sent to storage ponds along with plant liquid effluents containing low levels of borax. The clays contain low levels of pyrrhotite, a paramagnetic iron sulfide mineral, that is attracted to powerful rare-earth magnets (Mining Engineering, 2000b).

On May 1, 1999, U.S. Borax purchased the assets of Lake Minerals Corp., a trona mining operation on Owens Lake near Lone Pine in the central California mountains. Designated as U.S. Borax Inc., Owens Lake Operations, the facility would allow Borax to ensure control of its trona supply used in the borate refining process. Trona provided a cost-effective source of carbonates, which helped reduce scaling in the processing equipment. Owens Lake was the third largest trona deposit in the United States.

The 116-year-old Borax 20-mule team wagons were used in the 110th Tournament of Roses in Pasadena, CA, in 1999, and were placed on be permanent display at the Borax visitors center on the edge of the Boron Mine. The visitors center had been open 7 days a week since October 1997, marking the company's 125 anniversary of doing business in California. It was set up as an educational center for modern mining and the impact on minerals on daily life (U.S. Borax Inc., December 21, 1998, Twenty-mule team takes its final ride, accessed October 17, 2000, at URL http://www.borax.com/nonflashsite/company/news_20mule.html). The founder of the 20-mule team, Francis Marion "Borax" Smith, was buried in Mountain View Cemetery, Oakland, CA, in "Millionaire's Row" (Find a Grave, [undated], Frances Marion Smith "Borax", accessed April 7, 2000, at URL http://www.findagrave.com/pictures/3258.html).

The 849 employees at the Boron Mine processed about 3 million metric tons per year (Mt/yr) of ore (Rio Tinto Borax, 2001). Two new safety programs were instituted. A safety management audit training program trained employees to observe work practices and encouraged feedback. It transitioned from top-down model enforcement to bottom-up participation. A second program installed video cameras on the trucks to eliminate drivers' blind spots. The primary goal was to improve safety (Craig, 2000).

The Gerstley Borate Mine near Boron, CA, was closed because of the cost of meeting regulatory requirements, including fireproofing and replacing support timber. The run-of-mine ore was used in glazes as a secondary flux at midrange temperatures and a primary glaze at low temperature firing. The ore was popular in middle temperature glazes because its high melt fluidity produced a textured and variegated visual effect. The Gerstley ore was an aggregate of colemanite, ulexite, and hectorite. It also contained some limestone. Gerstley was named after a former president of the company (Gerstleyborate.com, [undated], What was Gerstley borate?, accessed May 24, 2001, at URL http://digitalfire.com/gerstleyborate/description.shtml).

Consumption

Total annual world consumption of borates was as follows: insulation, fiberglass, textile fieberglass, and heat-resistant glass (41%); ceramic and enamel frits and glazes (13%); detergents, soaps, and personal car products (12%); and agricultural micronutrients (6%).

Borate applications for glass consumption included the following five categories: borosilicate glass, ceramic frits and glazes, glass fiber insulation, porcelain enamels for steel and aluminum, and textile glass fiber. These five categories of glass have significantly different thermal, chemical, and mechanical properties, although their compositions contain chemicals drawn from the same list of about 10 oxides. Boron oxide allows the formulated glass to have high chemical durability, low thermal expansion, and low electrical conductivity. By using a computer simulation model, it is possible to predict glass properties from the oxide composition. Using models can lessen laboratory research time spent in product development by calculating new glass compositions that have the desired properties (Cook, 2000).

Glass fiber thermal insulation, primarily used in new construction, was a large area of demand for borates and was the principal insulating material used in the construction industry. Composed of very thin fibers spun from molten glass, fiberglass traps and holds air. Typically, between 4% and 5% of boron oxide is incorporated in its formulation to aid melting, to inhibit devitrification, and to improve the aqueous durability of the finished product.

Borates also were used in a range of products made from high-tensile-strength glass fiber materials. The process of producing glass fiber uses a borosilicate (e-glass) formulation that is continuously drawn through platinum alloy bushings into continuous 9-micrometer (μm) to 20-μm diameter filaments. Calcium aluminoborosilicate, e-glass, or textile fiberglass typically contains between 6% and 10% boron oxide.

The minerals colemanite and ulexite were used mainly for the production of ceramic frit on glazed tile, fiberglass, and glass wool. Because of variability of minerals, they must be milled to a fine particle size (200 mesh) and blended prior to use. The fineness of the grind eliminates coarse particles of quartz that could remain undissolved in the glass. Colemanite products were usually 75% to 85% pure and contained gangue in the associated minerals calcite, clays, and gypsum, and minerals that contain the elements aluminum, arsenic, iron, magnesium, silicon, strontium, and sulfur. Contained water in boron minerals can cause higher energy usage, increase stack emissions, decrease glass quality, and lower production rates. The water in calcium borate minerals is expelled at around 400° C accompanied by vigorous decrepitation of the ore, which can contribute to dust, causing greater refractory corrosion rates and increased particle emissions (Carr, 2000).

Slag is the waste steelmaking produces when unwanted impurities, such as silica, phosphorus, and manganese, are removed from the iron ore. A specialized borate was added to slag to allow the slag to cool slowly and prevent dust and mud. The fist-sized slag rocks formed were suitable for construction material (Borax Pioneer, 2000b).

Triphenylboron (TPB) and triisopropyl borate (TIPB) have been used by E.I. du Pont de Nemours and Co. (DuPont) to make nylon 6,6. For this process, adiponitrile is converted into hexamethylenediamine (HMD). HMD and adipic acid are the building blocks of nylon 6,6. The boron chemicals promote higher yields, but unlike catalysts, they are not reused, nor are they incorporated in the final product. Instead, they are hydrolyzed into boric acid before leaving the plant. The chemicals can be used as an agrochemical, catalyst, flame retardant, and fuel additive. DuPont would also be willing to

Digitized by Google

sell the boron chemicals for use in nylon intermediates manufacturing in an arrangement under which DuPont would license the adiponitrile technology and supply TPB and TIPB (Tullo, 2001b).

Boric acid was used in wallboard, also known as drywall or gypsum board or plasterboard, to increase the production line speeds, to save raw material, to reduce energy and shipping costs, and to improve the overall board quality. No new wallboard plant had been constructed in North America in the past 10 years. With the rise in residential and commercial building in North America, there was increased demand for wallboard.

Boron is 1 of 16 nutrients essential to all plants. Boron is essential to plant growth and can be applied as a spray and incorporated in fertilizer, herbicides, and irrigation water. Boron applied in May and June can be combined with calcium. For early season apples, boron can be applied post-harvest to provide adequate nutrition as buds begin to develop. During 2000, 18,628 t of boron micronutrients were applied on crops compared with 20,398 t in 1999. The largest region of use was in the west north-central, which used 8,297 t (Terry and Kirby, 2001).

In solution, borates form negative ions that can link with certain organic substances containing alcohol groups. This is an important role of boron in regulating metabolism. Too much borate concentration will turn the regulation into inhibition and stop cells from growing. Stopping cell growth rather than killing the cell makes borate a biostat rather than a biocide. It explains how and why borate compounds can be use to control so many different pests and why acquired resistance to borates is unlikely. The mild biostatic effect also makes borates not harmful to humans. Natural borate compounds have been shown to work against and to control algae, bacteria, fungi, and many insects like ants, beetles, cockroaches, fleas, flies, moths, termites, and wasps. Examples of widespread commercial use of the bacteriostatic properties of borates include additives in air conditioning systems, caviar, cooling fluids, cooling water, cosmetics, eye drops, in-can preservatives for paints, and metal lubrication (Lloyd, 2000).

Advanced Ceramics Corp. opened a $30 million world headquarters in Strongsville, OH, on February 29. The transfer of equipment and people was scheduled to be completed by the end of 2003. The company produced boron nitride and other nonoxide advanced ceramic powders, hot-pressed shapes, and chemical vapor deposition shapes and coatings (Advanced Materials & Processes, 2000).

U.S. Borax teamed with Osmose Inc., which was the leading chemical supplier to the wood preservation industry, and L-P Corp., which was the world's largest producer of oriented strand board. Osmose would provide borate-treated lumber through its many licenses, and L-P Corp. would incorporate borates into some structural panel products. U.S. Borax would supply Timbor® Industrial (disodium octaborate tetrahydrate) for lumber and plywood, and Composibor® (zinc borate) for engineered wood products (Bhatia, 2001).

Transportation

In 2000, U.S. Borax products from the mine were transported primarily by rail, although trucks were also used. The company ranked as the primary bulk shipper in California on the Burlington Northern Santa Fe Railroad, which had a fleet of more than 700 rail cars. Ocean transport was from the port of Wilmington, CA, where it had the only remaining privately owned berth in the harbor. It ranked as the largest exporter of high-value dry bulk products and among the top 10 shippers of ocean containers out of the ports of Los Angeles and Long Beach, CA. About 10 ships per year, with a capacity of 40,000 deadweight tons each, were loaded for locations around the world.

Antwerp, Belgium, which had the most central port location in Europe, had access to 188 major European cities. The industrial minerals market in Europe was characterized by high volumes of imported materials, mostly forwarded through the industrialized areas of Belgium, France, Germany, and the Netherlands for destinations in Central Europe, such as Austria, the Czech Republic, and Slovenia. The decision to import material was based on the geographic location, the range of service needed, and prices.

U.S. Borax used barges to ship borates from Rotterdam in the Netherlands to customers in Belgium, Eastern Europe, France, Germany, and countries even farther away. For small consignments, trucks can be more competitive than barges. Barges were the most efficient and reliable method of transporting goods in Europe, which had a 25,000-kilometer (km) network of navigable canals and rivers. Most of the large industrial areas could be reached by barge on waterways linking parts of the North, the Baltic, the Black, and the Mediterranean Seas and the Atlantic Ocean. In 1992, the 170-km canal linking the River Main to the Danube was opened in Germany.

The Trona Railway connects to the Southern Pacific Railroad between Trona and Searles Stations.

Prices

Prices of boron minerals and compounds produced in Argentina, Brazil, Turkey, and the United States are listed in table 4.

World Review

Argentina.—Borax Argentina S.A., which was a subsidiary of Rio Tinto plc., was the country's leading producer of borates (table 6). Borax Argentina mined borates at three deposits in Salta and Jujuy Provinces. Tincalayu Mine, originally developed in 1976, was Argentina's largest open pit operation and measured 1.5 km long, 800 m wide, and 100 m deep. The clay overburden averages 50 m and typically overlies 30 to 40 m of ore. Ore was trucked from the mine to a rail terminal at Pocitos, 120 km north of Tincalayu, and loaded on trains of 11 cars, each with a 30 t capacity. The Quijano plant was ISO 9002 certified. Consumption of boron products was in agriculture, glass, fiberglass, frits, and other applications (Baele, 2000)

The newest producer was Procesadora de Boratos Argeninos S.A., owned by Ferro Corp. and Canadian JEM Resources & Engineering, Inc. The project was purchased in 1999 from S.R. Minerals Ltd., which was an affiliate of Smokey River Coal Ltd., a Canadian coal producer. Tincal and ulexite mined at Loma Blanca were processed with magnetic separation and then calcining at Palpalá. A range of calcined and noncalcined products were produced containing 35% to 60% boron oxide.

Digitized by Google

Production was about 3,000 metric tons per month (O'Driscoll, 2001).

Norquímica S.A. was one of the few surviving boric acid manufacturers in Argentina. Ulexite was raked on the surface of the salars in Salta Province, spread out to dry, and trucked to the company's plant in Salta for concentrating. A portion of the ulexite concentrate is used as feed for the boric acid plant, where it is reacted with sulfuric acid.

Asia.—Albemarle was planning to offer zinc borate flame- and smoke-suppressing products in Asia under a commercial agreement with Borax Polymer Additive Group. The new zinc borate products broaden the company's range of halogen and halogen-free flame retardant systems. Albemarle's flame retardants fall under the umbrella of its polymer chemicals division, which generates about $450 million per year in sales (Chemical Market Reporter, 2000).

Bolivia.—Borate production was from companies that mined ulexite from Government concessions around Salar de Uyuni in the Bolivian Altiplano. Cia. Minera Tierra S.A. had large ulexite concessions near the Chilean border and produced dried and washed grades for export. Reserves were in the order of 5.5 Mt of boron oxide. In addition to ulexite, Tierra produced boric acid and in 1999 exported 12,500 t worldwide. The operation employed 250 in Bolivia and 45 in Chile.

On August 28, Bolivian (FELCN), Chilean (OS7), and U.S. (DEA) antidrug authorities descended on Tierra and its Chilean sulfuric acid supplier, Alco Ltda. Thirteen executive staff and employees were arrested. In December, the Bolivian executives were released, but the seven Chilean employees were detained. The charge was based on 7,000 to 15,000 t of sulfuric acid allegedly being deviated from the production of boric acid to the illegal cocaine processing plants in the Chapare district of Bolivia. The volume of sulfuric acid in question represented about 35% of Tierra's consumption in the production of boric acid. Judgement on the case in Bolivia was expected to begin in March 2001 (O'Driscoll, 2001).

The case, the first of its kind, highlighted potential problems that could arise with industrial minerals companies that need to consume or process predetermined "precursors," such as soda ash or sulfuric acid. These commodities were recognized by antidrug agencies as being the same level as "controlled substances" in narcotics culture (O'Driscoll, 2001).

The Pampa borax deposit, which was owned by Champagne Miner Rio Grande S.A., had ulexite ore with a boron oxide content of between 30% and 34% and 1.7 Mt of proven reserves. The deposit included 9 concessions comprising 4,480 mining claims and was located in Nor Lapis Province, south of the Salar de Uyuni.

Chile.—Borax Argentina, S.A., had 198 employees working at the Tincalayu, the Sijes, and the Porvenir Mines and the Campo Quijano refinery. The mine at Tincalayu, Salta, is Argentina's largest open pit mine, measuring 1,500 m wide, 500 m long, and 100 m deep. The main minerals mined are tincal, ulexite, colemanite, hydroboracite, and kernite. The mine operates at a rate of 100,000 t/yr. Energy is supplied by two generation plants, which produce 146,000 kilowatts per month (Rio Tinto Borax, 2001).

Quimica e Industrial del Borax Ltda. (Quiborax) mined ulexite from Salar de Surire, which was the largest ulexite deposit in the world. Reserves were estimated to be 1,500 t. The deposit was located at an altitude of 4,250 m in Monumento Natural de Surire, a national park. Production in 2000 was 380,000 t of crude ulexite. The ore was trucked to the El Aguila production facility north of Arica. Some of the ulexite was dried and sold, and the balance was reacted with sulfuric acid to produce 36,000 t of 98% to 99.9% boric acid. The majority of production was exported through the port of Arica.

Quiborax's other plants included a new granulated ulexite plant, which produced agricultural ulexite ranging between 10% to 13% boron oxide, and another special ulexite plant, which produced different types of boron ranging product between 30% to 45% boron oxide for specific market requirements (O'Driscoll, 2001).

Champagne Minera Salar de Atacama was 100% owned by Sociedad Quimica y Minera de Chile S.A. (SQM). A large integrated facility was scheduled to begin production of 16,000 t/yr of boric acid as a byproduct of potassium sulfate production. SQM was reported to be purchasing boric acid for resale until the plant could begin boric acid production. SQM also produced ulexite from reserves in excess of 7 Mt boron oxide content at Salar de Ascotán and Salar de Carcote (O'Driscoll, 2001).

China.—Over 80% of the country's borates resources were in Liaoning and Jilin Provinces. The ores were primarily metamorphic deposits containing primarily ascharite, a magnesium borate. Other production was from playa lakes in Qinghai, where borate minerals, such as ulexite, hydroboracite, and borax, were produced from brines near the Qinghai-Tibet plateau (O'Driscoll, 2001).

China announced Shangha's plans to be the world's first city to build a commercial maglev train (Denver Post Newspaper in Education, 2001, Magnetic levitation train, accessed March 22, 2000, at URL http://www.colokids.com/indexd4.htm).

India.—Submarginal borax reserves occur in the Puga Valley Districts of Jammu and Kashmir. In Rajasthan State, the bitterns from Lake Sambhar were reported to contain about 0.5% borax.

Italy.—Rio Tinto Borax appointed Milan-based Novaria Chemicals as its exclusive distributor of its Firebrake range of fire retardant polymer additives in the Italian market. Novaria provided expertise in the storage, handling, and distribution of plastic additives (Chemical Market Reporter, 2001).

Kazakhstan.—More than 100 boron deposits have been discovered in northern Prekaspiy. Boron deposits of the Inder groups were concentrated in the gypsum of salt domes and salt rock masses. Borates associated with gypsum include ascharite (szaibelyite), hydroboracite, inyoite, and ulexite. At two sites, dredging by means of drag lines took place at a depth of 15 to 20 m below water level. Borate ore reserves were reportedly estimated to be 2 Mt, but the undiscovered resources could reach 120 Mt of 9% boron oxide.

Peru.—Inkabor S.A., owned by the Italian Colorobbia Group, mined ulexite at Laguna Salinas, which is 80 km east of Arequipa. The open pit operation produced from 150,000 to 180,000 t/yr of ulexite ore during 6 or 7 months of mining. Large stocks were maintained for sales during the winter season. The crude ulexite was washed to produce a concentrate. The calcining plant operated 24 hours per day to produce calcined ulexite in granular and powdered forms. Ulexite was supplied to Oquendo for boric acid production. Oquendo's plant in Arequipa had the capacity to produce 12,000 t/yr of boric acid and 15,000 t/yr of concentrated ulexite.

Digitized by Google

Russia.—In August, 1999, Russia's sole borates producer, JSC Bor, was reorganized and renamed JSC Energomash-Bor in response to a move by Russian power equipment supplier JSC Energomash to become more involved in the borates business. In mid-2000, Energomash-Bor was preparing its second boric acid production line for commissioning, following a 9 month closure. The company also tested a nitrate method of processing datolite ore, which may permit a savings in power consumption. The refurbished plant was expected to double boric acid production and increase output of other boron products to between 100,000 to 140,000 t/yr (O'Driscoll, 2001).

Serbia and Montenegro.—Ras-Borati Ltd. began drilling the Piskanja boron deposit in the Jarandol Basin located near Baljevac in southern Serbia. Ras-Borati, which was established in February 1997, was a 50-50 joint venture between Erin Ventures Inc. of Kelowna, Canada, and Electroprivreda, the national power company of Serbia. A drilling program was planned to raise the status of a 7-Mt block of reserves that graded 35% to 39% ore from indicated to proven. The minerals were primarily colemanite and ulexite. Ras-Borati also held rights in the Pobrdjski Potok borate deposit in the Jarandol Basin. Proven and probable reserves of 140,000 t of ore reportedly averaged 37% boron oxide.

Tajikistan.—A skarn borosilicate deposit at Ak-Arkhar, which was situated at an elevation of 4,400 to 5,000 m, reportedly had measured and indicated reserves of danburite ore that exceed 80 Mt.

Turkey.—Turkey's boron operations were under the control of Eti Holding AS, formerly Etibank, through its subsidiary Eti Boron Inc. Co. Boron production was managed by five operations, four of which were integrated mine and plant facilities and one, at Bandirman port, was a plant facility. Additional capacity was planned for startup in 2002 with a 160,000-t/yr plant for borax pentahydrate at Kirka and in 2003 with a 100,000-t/yr boric acid facility at Emet (O'Driscoll, 2001).

United Kingdom.—Rio Tinto Borax, a wholly owned subsidiary of Rio Tinto, was dedicated to the mining, refining, and marketing of borates. Borax produced more than 1 Mt/yr of product from ore bodies in the United States and Argentina, employing 1,700 people worldwide. As a miner and refiner, Borax managed the environmental, social, and economic impact of its operations, applying the same standards at each location. These activities were classified under the headings of safety and stewardship. Borax believed its contribution to sustainable development to be that its operations have low environmental impact and make a positive social contribution, that its borate products enhance standards of living and contribute to economic development, and that borates measure up favorably in terms to most substitute products. To aid the mining industry in achieving sustainable development, the Industrial Minerals Association was formed as an industry association. In addition, a number of the world's largest mining companies established the Global Mining Initiative as a case for mining as a positive factor towards sustainable development. This was projected to lead to a major conference on mining and sustainable development in 2001 (Edbrooke, 2000; Mining Minerals Sustainable Development Project, [undated], Stainable development raises as many questions as it answers, accessed June 12, 2001, at URL http://www.globalmining.com/index.asp).

Borax Europe Ltd., a subsidiary of Rio Tinto Borax, was involved in a court case against one of its former employees over an alleged breach of confidentiality. The case involved a graph that was placed on the private website of the former employee. The company claimed that the graph disclosed information that was confidential to the company. At the August hearing, the employee voluntary agreed not to disclose any confidential information and to return the material used to Borax (Industrial Minerals, 2001).

Uzbekistan.—An oil and gas condensate deposit at Dzhartchi had the potential to produce 377 t/yr of boron oxide at a pumping rate of 4,000 cubic meters per day for more than 20 years.

Current Research and Technology

Millennium Cell plc of Eatontown, NJ, is developing a chemical storage technology based on sodium borohydride. A clear aqueous solution of about 30% sodium borohydride is exposed to a proprietary catalyst to yield hydrogen and sodium borate byproducts, resulting in a milky solution of spent fuel. Millennium is forming a joint development with Rohm and Haas Co., a major sodium borohydride supplier, to come up with a better process by closing the loop in the stream and recycling the sodium borate back to sodium borohydride. Millennium stated its storage density rivals liquid hydrogen at about 63 grams per liter (Tullo, 2001a).

A graduate student in chemical engineering at several universities has designed copolymers that can be applied to cells or tissues to prevent adhesion of antibodies or to block the body's response to its own tissues during wound healing. These copolymers could be used to coat organs prior to transplantation to prevent rejection. The backbone of these copolymers is a poly (l-lysine), and grafted onto the backbone are phenylboronic acid and poly ethylene glycol (Rouhi, 2000).

Sodium perborate bleaches stains extremely well at above 60° C temperatures as hydrogen peroxide releases oxygen into the wash. At temperatures of about 40° C, such activators as tetraacetylethylenediamine and nanayoyloxybenzenesulfonate can be used to release peracids that are effective oxygen sources. A new catalyst can release oxygen below 40° C that works like a biological enzyme, while suppressing any unwanted chemical reactions (Borax Pioneer, 2000a).

Albemarle Corp. and Borax Flame Retardant Group reached an agreement to develop joint applications for zinc borate in flame retardants. The goal is to increase the availability of halogen and halogen-free flame retardants to the polymer industry. Zinc borates are currently used in epoxy, plyamide, and polyvinylchloride compounds, but there are potential opportunities in engineering plastics, styrenics, and other resins (Industrial Minerals, 2000).

Boron-bearing antioxidants used in refractory bricks increase the resistance of the brick to oxidation and slag corrosion. The best results were achieved with combinations of aluminum boride with boron carbide and calcium boride when compared with zirconium boride additives (Hunold, 2000).

Colemanite and borax are the least and most soluble boron minerals of commercial importance, respectively. Boron minerals, such as colemanite and borax, which use primary amine collectors exhibit collector precipitation above a critical pH, determined by amine content. The collector precipitation

Digitized by Google

was attributed to the formation of amine hydroborate. Studies indicate that the precipitate is dodecylamine and may enhance the floatability of colemanite (Akin and others, 2000).

A new family of weakly coordinating anions could greatly improve the activity of metallogen catalysts used in industrial olefin polymerizations according to researchers at Dow Chemical Co. Aluminum or boron is used in the anions (Chemical & Engineering News, 2000d).

Scientists at Osaka University, Japan, have developed a new catalytic reaction that adds multiple alkyl groups to aromatic rings using a norbornyl group on the phenyl ring. The process repeats itself, proceeding around the ring until steric factors interfere. The reaction of pheylboronic acid and 2-norborene in the presence of a rhodium catalyst yield primarily the tetranorbornylbenzene ring. The method provides a method for the synthesis of a unique class of sterically encumbered aromatic molecules (Chemical & Engineering News, 2000c).

Chemists at Emory University, Atlanta, GA, discovered a palladium-catalyzed coupling of thiol esters with boronic acids to produce ketones under mild conditions. Because the reaction proceeds even at a pH of 4.5, the conditions are very mild and will tolerate functional groups that would not survive standard cross-coupling systems. The reaction is mechanistically distinct from other processes where a base is normally used. The coupling of boronic acids to thiol esters expands boronic acid coupling into completely new fields (Zurer, 2000).

Chemists at the University of California, Irvine, CA, copolymerized two olefin monomers into an ethylene-polylene copolymer. Dimethylsulfoxomium methylide can be polymerized by triethylborane to make linear polymethylene, more commonly known as polyethylene. The research opens the door to designer polymers not obtainable through conventional polymerization of olefin monomers (Chemical & Engineering News, 2000e).

A new superacid powerful enough to protonate C_{60} to give HC_{60}^{+} as a stable ion in both solution and solid state was developed by the University of California, Riverside, CA. The superacid is based on the hexahalocarborane anion $[H(CB_{11}H_6X_6)]$, where X = Cl or Br. The new superacid and oxidant may allow the investigation of processes and reactive species previously difficult or impossible to study (Chemical & Engineering News, 2000b).

Physicists at Aoyama-Gakuin University, Japan, announced that magnesium diboride became superconductive when cooled to or below 39 K. This range of superconductivity is 16 K higher than any other simple metallic compound. The possibility is that magnesium-diboride-based material may be able to carry more current than the copper oxide superconductors. Furthermore, magnesium diboride may not need to be cooled with liquid helium as conventional superconductors are, but rather by electrical refrigeration (Dagani, 2001).

The world's fine chemicals industry displayed its wares and expertise in Milan, Italy, for the Conference on Pharmaceutical Ingredients. Companies introduced new intermediates in their catalogs and unveiled new technologies for producing chemicals to special order. Digital Specialty Chemicals, Dublin, NH, offered oxazaphospholidines that were made by reaction of phenylphophine-borane with either ephedrine or pseudoephedrine, which are opposites and thus may induce opposite configurations in products (Stinson, 2000).

A senior scientist at Haldor Topsoe Research Laboratories, Lyngby, Denmark, prepared a barium-promoted boron nitride catalyst to synthesize ammonia. The catalyst was prepared from boron nitride crystals and aqueous solutions of ruthenium nitroso nitrate and barium hydroxide (Chemical & Engineering News, 2001).

Boriding, the diffusion of boron into the surface of metals, increases the wear and corrosion resistance of the metals. Boron is an element of relatively small atomic radius, which allows it to diffuse into a variety of metals, such as ferrous metals, metal-bonded carbides, and nickel alloys. Boron reacts with ferrous alloys to form Fe_2B with Knoop hardness in the range of 1,500 to 1,700. The significant increase in case hardness results in substantial reduction of wear and galling (Cataldo and others, 2000).

Laser surface engineering (LSE) is a surface modification process in which a high power laser beam melts a ceramic powder precursor along with a thin layer of substrate to produce a laser melt zone. LSE of titanium diboride coating is a two stage process. In stage 1, a precursor layer of titanium diboride in a water-based organic solvent is deposited on an AISI 1010 steel substrate. In stage 2, an industrial grade laser melts a thin layer of the steel substrate. The titanium diboride powder becomes embedded in the molten steel creating a composite coating. The most significant properties of the coating are its corrosion resistance, modulus of elasticity, hardness, oxidation resistance, smoothness, strong interface, and wear resistance (Agarwal and Dahotre, 2000).

Room-temperature ionic liquids, formerly called molten salts, typically consisting of nitrogen-containing organic cations and inorganic anions are potential "green" [enviromentally friendly] designer solvents because they have no detectable vapor pressure and can make synthetic processes more efficient, resulting in a lower usage of raw materials. The organic cations are mated with inorganic anions, such as boron tetrafluoride. Ionic liquids are inherently ionically conductive, can mitigate self-discharge, and are virtually nonvolatile, nonflammable, and less toxic than conventional electrolytes. The electrochemical potential is usually much greater than for aqueous electrolytes. There is substantial interest in using ionic liquids as battery electrolytes. Researchers at the U.S. Air Force Academy are studying a dual intercalating molten electrolyte (DIME) battery. Research has shown that boron tetrafluoride works in the DIME battery (Freemantle, 2000).

Outlook

The demand for boron in the United States is expected to remain strong. New applications in gypsum board and strong demand in the glass industry are expected to increase consumption. Boron compounds and chemicals can reduce energy use in the creation process of many products. This may become an important sector if energy costs continue to rise. Although South America has large reserves of boron minerals, location, infrastructure, and processing problems have delayed significant production. The world production amounts for Turkey in table 7 do not accurately reflect production because some ore that was once exported is now being consumed as boron products for sale to Asia and Europe. World demand is expected to grow, primarily in the glass industry.

BROMINE

By Phyllis A. Lyday

Domestic survey data and tables were prepared by Maria Arguelles, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Bromine is a natural element widely found in nature, principally in seawater, salt lakes, and underground brines associated with oil. The quantity of bromine sold or used in the United States was 228 million kilograms (Mkg) valued at $206 million (table 1). The value of bromine sold or used was $0.90 per kilogram (table 3). Primary uses of bromine compounds were in flame retardants (40%), drilling fluids (24%), brominated pesticides (mostly methyl bromide) (12%), water-treatment chemicals (7%), and others, including photographic chemicals and rubber additives (17%) (Chemical Market Reporter, 1999a). International distribution of bromine production for 2000 was estimated to be as follows: the United States, 45%; Israel, 35%; China, 9%; the United Kingdom, 5%; and other countries, 6% (table 6). Because of depleting reserves, distribution and economics, environmental constraints, and the emergence of Israel as the world's second largest producer with 36% of the world market, the U.S. portion of world production decreased steadily since 1973, when the United States produced 71% of the world supply, to 42% in 2000.

Legislation and Government Programs

Methyl bromide was listed as a class I ozone-depleting substance in the 1990 Clean Air Act (CAA) and was scheduled to be phased out in the United States by January 1, 2001. The U.S. Congress extended the phase out of methyl bromide until January 1, 2005, to coincide with the deadline for developed countries under the Montreal Protocol on Substances that Deplete the Ozone Layer. Under the Clean Air Act Amendments of 1990 (Public Law 101-549), U.S. production and imports of bromine must be reduced from 1991 levels as follows: 25% by 1999; 50% by 2001; 70% by 2003; and a full ban by 2005. Domestically, methyl bromide had proven to be a difficult pesticide to replace because of its low cost and usefulness against a large variety of agricultural pests. The amendment allowed for the exemption of critical uses of methyl bromide that have not been yet defined. The dominant use was for preplanting soil treatments. It also was used for structural applications, such as termite treatments. The United States consumed methyl bromide as a preplant fumigant for tomatoes (30%), strawberries (19%), and peppers, (14%). About 50% was consumed in California and 30% in Florida. (Hess, 2000). Three producers, Albemarle Corp., Great Lakes Chemical Corp., and Israel's Dead Sea Bromine Co. Ltd. (DSB), were the major manufacturers. Under the Montreal Protocol, developing countries had until 2015 to phase out methyl bromide production.

A report by environmental groups that predicted a national assessment of how global warming might affect the U.S. climate over the next 100 years was criticized by the Competitive Enterprise Institute as "a scientifically dishonest, alarmist document based on junk science." Critics stated the report sought to advance "a political agenda rather than look at the state of the science and its uncertainties involving the theory of climate change." Other deficiencies were predictions about future weather conditions that were "simply not scientifically possible with current technology" (Chemical

Bromine in the 20th Century

In 1901, production of bromine from brines associated with salt production was reported by the U.S. Geological Survey from Michigan, Ohio, Pennsylvania, and West Virginia to be 245,867 kilograms (542,043 pounds) valued at $154,472. The consumption was primarily for use in medicine, photography, and analytical and experimental chemistry. As bromine became more readily available, uses increased and included dissolving gold and separating it from platinum and silver, acting as an oxidizer, and uses in disinfectants, salts, and aniline dyes. During World War I, bromine was used extensively in asphyxiating gases in Europe. By 1918, bromine production had increased in quantity to 783,426 kilograms (1,727,156 pounds) valued at $970,099. In 1921, tetraethyl lead was used to reduce knock or pinging in internal-combustion engines. Bromine sold by producers in 1924 increased to 922,519 kilograms (2,033,804 pounds) valued at $594,685 as a result of use in the manufacture of ethylene dibromide used as a scavenger for tetraethyl lead. In 1924, E.I. du Pont de Nemours & Co. Inc. conducted successful experiments to produce bromides from seawater on a specially equipped ship named U.S. *Ethyl*. Dow Chemical Co. found bromine-rich brines in Midland, MI, and began production in 1925. By 1930, over 1,350 metric tons (3 million pounds) of bromine was produced. Bromine production began in Arkansas in 1965, and Arkansas quickly became the world's leading bromine producer. Ethylene dibromide continued to be the major use for bromine until lead was banned in gasoline in 1976 and was phased out by 1978.

In 2000, U.S. production of 228 tons valued at $206 million came from brines in Arkansas and Michigan. Bromine markets included the oil- and gas-well drilling industry, automobile tires, soil and grain fumigation, photographic papers and chemicals, gold ore processing chemicals, fire retardants for plastics, and biocides in indoor hot tubs, swimming pools, and recirculatory cooling systems.

Market Reporter, 2000e).

The U.S. Environmental Protection Agency (EPA) announced a new office for information management, information policy, and technology stewardship that would be headed by a national program manager. The new office included the highly visible Toxics Release Program, which had been run in the past in the Office of Pollution Prevention and Toxics. The data collection and analysis functions that had been scattered throughout the agency would be consolidated to include environmental statistics, one-stop reporting, single-facility identification, and watershed information (U.S. Environmental Protection Agency, [undated], Pesticides, toxics and chemical projects and programs, accessed April 25, 2000, at URL http://www.epa.gov/epahome/pestoxpgram.htm).

Bromine was taxed under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (Superfund) (Public Law 96-510) that had gone through two reauthorizations since its enactment in 1980. The 1986 Superfund Amendments and Reauthorization Act (Public Law 99-499) made considerable changes to the remedy selection component of the law. A second reauthorization in 1990 extended only the program and its taxing authority. Superfund taxes on industry, which generated $1.6 billion per year, had not been collected since December 1995. The Superfund Trust Fund was projected to run out of money in 2000. By yearend, the Superfund had not been amended.

The EPA, the Environmental Defense Fund, and the American Chemistry Council announced that 192 of the Nation's largest chemical and oil companies, including 2 that produce bromine, had volunteered to ensure that approximately 1,100 commonly used chemicals were screened for basic toxicity; the companies were Chemical Manufactures Association (CMA) members (Johnson, 1999). The agreement was a significant step toward gathering complete screening data for 2,800 high production volume chemicals that were used or imported in quantities exceeding 454 metric tons per year (t/yr) (1 million pounds per year). CMA's Internet tracking publicly displayed the chemicals and timetables set for the companies (Chemical Manufacturers Association, [undated], HPV challenge website, accessed April 25, 2000, at URL http://www.cmahq.com). The Council of Chemical Associations, an international industry trade association, set a goal of testing 1,000 chemicals by 2004. The toxicity testing would be carried out under a cost-sharing program operated by the Organization of Economic Cooperation and Development, which comprised 29 countries, including the United States. The Synthetic Organic Chemical Manufacturers Association announced its support of the program as a result of commitments made by the EPA.

The EPA published in the Federal Register of December 7, 1999, its final rule for the revisions to the underground injection control regulations for class V injection wells. A study was conducted to develop background information used to evaluate the risk of these wells to underground sources of drinking water and to determine whether additional Federal regulation was warranted. Bromine was included in volume 9, "Spent Brine Return Flow Wells." In Arkansas, all 74 of the class V spent brine return wells were associated with facilities that produced bromide compounds from brine extracted from the Smackover Formation 6,000 feet below the lowermost underground source of drinking water (USDW). The chemical characteristics of the injected spent brine were determined primarily by the characteristics of the brine that was withdrawn for processing. In Arkansas, available data indicated that concentrations of barium and boron in spent brine routinely exceed primary maximum contaminant levels or health advisory levels. Arkansas was an underground injection code (UIC) primacy state for class V wells, so the Arkansas Oil and Gas Commission had jurisdiction over permitting, construction, and operation requirements. In Michigan, 24 spent brine wells were associated with production of magnesium, bromide, and calcium compounds from the Filer Sandstone Formation 2,000 feet beneath the lowermost USDW. In Michigan, EPA region 5 implemented the UIC class V program. In addition, the Geological Survey Division of the Michigan Department of Environmental Quality had authority to establish standards for construction, testing, operations, and plugging and abandonment of mineral wells and to permit such wells (U.S. Environmental Protection Agency, September 30, 1999, The class V underground injection control study—Volume 9—Spent brine return flow wells, accessed April 18, 2001, at URL http://www.epa.gov/safewater/uic/classv/volume9.pdf).

The U.S. Department of Transportation published a notice of final rulemaking for the Research and Special Programs Administration amending certain requirements in the hazardous materials regulations to enhance safety and to align with international standards. Changes to the hazardous materials table included removing 1-chloro-3-bromopropane and adding 1-bromo-3-chloropropane (U.S. Department of Transportation, 2000).

The Consumer Product Safety Commission held public hearings in 1998 to receive scientific and technical information relating to the toxicity, exposure, bioavailability, and environmental effects of flame retardant chemicals, including bromine compounds, that may be suitable for use in residential upholstered furniture. The Commission would evaluate the information obtained from the hearings as part of its deliberations on whether to propose a standard to address the hazard associated with small open-flame ignitions of upholstered furniture. At yearend 1999, the study was still in the information-gathering stage. In 2000, the study was in the draft stage.

The U.S. Department of Justice (DOJ) and the European Commission had been investigating the bromine industry for possible violations of antitrust laws. DSB pleaded guilty and paid a $7 million criminal fine for participating in a price-fixing conspiracy to eliminate competition in connection with the sale of certain flame-retardant products [tetrabromobisphenol-A (TBBA) and decabromodiphenyloxide] and the fumigant methyl bromide in the United States. Great Lakes had been granted U.S. amnesty from criminal prosecution in the investigation. DSB was charged with fixing prices in the United States between July 1995 and April 1998. The continuing investigation was being conducted in the DOJ Antitrust Division's field office in Dallas and the Federal Bureau of Investigation (Chemical Market Reporter, 2000g; Industrial Minerals, 2000e).

The EPA asked the chemical manufacturers to voluntarily test 23 substances, including ethylene dibromide, to which children were exposed in everyday life. The EPA would use data generated in the first round of its Voluntary Children's Chemical Evaluation Program to examine the risk from chemicals found in the human body that come from food,

Digitized by Google

water, or air. The agency planned to evaluate and revise the program after the first tests and to expand it to include more chemicals (Hogue, 2001).

Production

Domestic production data for bromine were developed by the U.S. Geological Survey from a voluntary survey of U.S. operations. Of the operations to which a survey request was sent, six responded, representing 100% of total elemental bromine produced (table 1).

Albemarle's bromine production included three plant sites in south Arkansas with the addition of their new satellite facility in Union County, which was started up in July 2000. Albemarle had 31 bromine production wells, 6 of which also produced oil. Brine wells were twice as wide and twice as deep as typical Arkansas oil wells, and the brine that was produced exceeded 110° C (230° F). Albemarle owned 17.4% of the production from the west unit operated by Great Lakes in Union County and, as a result, produced bromine at their satellite plant from five additional wells in the unit.

Albemarle reported that the 50,000-t/yr TBBA plant was operational in Magnolia, AR. An improved TBBA, marketed under the trade name SAYTEX CP-2000, was widely used in many plastics systems. CP-2000 was used in reactive monomer in polycarbonates and epoxy polymers and was a major reactive component in epoxy oligomers used as an additive (nonreacting) flame retardant in acrylonitrile-butadiene-styrene systems. Albemarle began producing CP-2000 in late 1999 by use of a patented continuous reacting process. This distinguished CP-2000 from all other competitive offerings of TBBA that were produced by a batch reaction process.

Bromine flame retardants were used in electronic equipment to increase the fire resistance of the plastic housings and the computer printed circuit boards. TBBA also was used in carpets, computer housings and electrical connectors, and office furniture (Warren, 2000). These applications included communications, construction, electronics, textiles application, and transportation (42%). According to Albemarle, other bromine derivatives end uses were: pharmaceuticals, photography, rubber, and water treatment (30%); gasoline additives and oilfield completion fluids (20%); and agricultural chemicals and fumigants (15%) (Chemical Market Reporter, 1999b). Albemarle received EPA approval for Stabrom™ 909 biocide (Chemical Market Reporter, 2000a). Albemarle expanded sales of brominated biocides to the 50 States and Europe. Albemarle also operated two bromine derivatives plants in France.

Albemarle and Borax Polymer Additives Group signed an agreement that allowed Albemarle to offer zinc borate flame- and smoke-suppressing products in Asia. Zinc borate can replace antimony oxide as a synergist and can be combined with other mineral-based additives to be used as a synergist with SAYTEX flame retardants (Chemical Market Reporter, 2000a).

Albemarle purchased Ferro Corp.'s Pyro-Chek® flame-retardants business along with a plant at Port-de-Bouc, France. Ferro retained ownership of its Hammond, IN, facility, but stopped manufacturing brominated polystyrene flame retardants at that site (Chemical Market Reporter, 2000b).

Great Lakes Chemical continued production of bromine from brines at four plants in Arkansas. The company also owned Associated Octel Co. Ltd. of the United Kingdom. Great Lakes reached an agreement to acquire Aqua Clear Industries LLC. Aqua Clear's products and retail markets were complementary to those of the Great Lakes subsidiary Bio-Lab, Inc. (Chemical Market Reporter, 2000h). Bio-Lab received regulatory clearance from the U.S. Food and Drug Administration for the use of BromiCide® in the manufacture of food-contact paper and paperboard.

TETRA Technologies, Inc. was one of the largest users of brominated products in the world. Calcium, sodium, and zinc bromide, collectively referred to as clear brine fluids (CBFs), were used in oil and gas applications. CBFs have high specific gravities and were used in completion and workover activities to reduce the likelihood of damage to the well bore and productive pay zone. Calcium bromide and zinc bromide were purchased from two domestic and one foreign manufacturer, and TETRA recycled calcium and zinc bromide CBFs repurchased from its oil and gas customers. The West Memphis, AR, facility produced calcium bromide and zinc bromide using zinc-containing sludge from electroplating operations and low-cost hydrobromic acid. TETRA began operation of merchant bromine, calcium bromide, and sodium bromide plant at the Dow Chemical Co. Ludington, MI, facility in mid-1998 using purchased crude bromine from Dow's calcium-magnesium chemicals operation. The liquid sodium bromide was sold to the industrial water treatment markets. TETRA also owned a plant in Magnolia, AR, that was designed to produce calcium bromide but was not operational in 2000. Approximately 13,400 hectares (33,000 gross acres) of bromine containing brine reserves in the vicinity of the plant were under lease (TETRA Technologies, Inc., 2000).

Consumption

Global estimates of world market share of brominated flame retardants (BFR) listed Great Lakes Chemical with 31%; Albemarle with 23%; DSB with 22%; and others with 24%. The demand for BFR was expected to reach 680 Mkg (1.5 billion pounds) by 2003, according to Cleveland-based Freedonia Group. Merrill Lynch estimated sales from BFR to be $210 million for Albemarle. Salomon Smith Barney estimated that Great Lakes sales were $271.7 million (Lerner, 2000). It was estimated that the world market for flame retardants for plastics stood at approximately $2.2 billion and would grow at 5% to 6% per year through 2003 (Chemical Business Newsbase, 1999c).

There were many different flame retardants that included bromine, chlorine, phosphorus, nitrogen, and other elements. Flame retardants are chemicals that suppress the combustion process. They prevent the spread of fires or delay the time of flashover so that people have additional time to escape. It is estimated that BFRs accounted for 39% of the worldwide market in 1998. Consumption by final application was reported as follows: electronics and electrical, 56%; building and construction, 31%; textile, 7%; and transformers, 6%. The distribution of BFR use in electrical and electronic components use was reported as follows: household appliances, 59%; printed wiring boards, 30%; connectors and relays, 9%; and wire and cabling, 2%. In 1999, consumption by region was as follows: Asia, 56.2%; the Americas, 28.7%; and Europe 15.1% (Bromine Science and Environmental Forum, 2000, An

Digitized by Google

introduction to brominated flame retardants, accessed April 15, 2000, at URL http://www.bsef.com).

Albemarle's fine chemicals division also included surface actives, bromine, and oilfield chemicals. The company had manufacturing units in Feluy, Belgium; Port-de-Bouc, Thann, France; and Teesport, United Kingdom. The Teesport facility functioned as a custom manufacturing and oilfield chemicals plant.

The EPA's methyl bromide phaseout program stated that those applications still using methyl bromide by 2005 would do so because they had no choice. Methyl bromide was still the common chemical used to limit the spread of damaging insect populations around the world. The U.S. Department of Agriculture recommended the use of methyl bromide to treat wood packaging materials from China because of the lack of good alternatives. A voracious, nonnative insect pest had been found in material at 26 scattered warehouse and residential sites in 14 States. China could end up having to use more than 12,500 metric tons (t) of methyl bromide to treat wood destined for the United States. This would represent a 75% increase in use in Asia compared with 1996 levels for all applications, including soil treatment. The EPA figures showed that only 4,070 t, or about 6% of all methyl bromide used globally, was used to fumigate timber worldwide in 1996 (Reisch, 1998).

Pesticides, such as bromine compounds, were used to protect food from pests, such as bacteria, insects, mold, rodents, and weeds. In 1996, Congress passed the Food Quality Protection Act (FQPA) to improve the safety of food and to protect the public from exposure to pesticides. With the passage of this act, the jurisdiction of food-contact antimicrobials shifted from the Food and Drug Administration to the EPA. The EPA asserted that conclusions concerning the dangers of pesticides in food were not credible and were unnecessarily alarmist (Chemical Market Reporter, 1999c). The EPA set standards on the amount of pesticides that may remain on food if pesticides were applied. The FQPA set a tougher standard for pesticide use on food. By 2006, the EPA was required to review all old pesticides safety standards to make sure that their use on food met the new safety standard. If a pesticide was authorized that did not meet the safety standard, then the EPA would work with grocery stores to inform consumers of such pesticides and foods that might contain them.

World Review

Publication of the International Organization for Standardization (ISO) 9000 standards was planned for November 2000. Bromine operations were part of the 200,000 ISO-9000-based quality-management systems being operated worldwide to ensure internal efficiency and customer specified requirements for the product (International Organization for Standardization, [undated], ISO revisions, accessed July 2, 1999, at URL http://www.bsi.org.uk/bsi/services/isorevs.htm; International Organization for Standardization, [undated], Welcome, accessed July 2, 1999, at URL http://www.iso.ch).

Azerbaijan.—The Neftchala iodine-bromine plant produced 4,000 t/yr of bromine from waters from oil wells in the Neftchla and Khillinsky oilfields, Prikurinsky Basin. The bromine reserves were estimated to be 100,000 t. To modernize and commission the plant, an investment of $1.4 million was required (Industrial Minerals, 2000c).

China.—Ocean Chemicals Group, Asia's largest elemental bromine producer, opened its first European sales agency in Old Glossop, United Kingdom. The agency planned to market bromine and bromine derivatives produced in China. The group produced 75,000 t/yr of bromine and bromine derivatives with sales estimated to be $1.2 billion per year (Chemical Business Newsbase, 1999b).

Construction began on the first phase of a bromide manufacturing joint venture in Weifang, Shandong Province. The venture was split between the Dead Sea Bromine Group and Haiha Group of Weifang. The new plant would produce a range of high-technology products of which the company planned to export 60% (Industrial Minerals, 2000b).

Denmark.—The Danish Environmental Protection Agency had drawn up a plan to progressively limit and stop the use of BFRs. A major part of BFR consumption was in imported goods, such as cars, computers, and television sets. The plan contained a large number of initiatives, such as build-up knowledge, information to consumers, international regulation and cooperation, national agreements, standardization, and subsidies for the development of alternatives to BFRs (Ministry of Environment and Energy, 2000, Danish Environmental & Energy Newsletter—Brominated flame retardants—Denmark is to limit the use of brominated fire retardants, accessed September 14, 2000, at URL http://www.mex.dk/uk/bromin.asp).

European Union.—The European Commission created three separate pieces of legislation out of the original draft directive on waste electrical and electronic equipment, which served to intensify the focus on BFRs. Under the draft, substitution of other flame retardants for polybrominated biphenyls (PBB) and polybrominated diphenylethers (PBDE) in electrical and electronic equipment was required to be completed by January 1, 2008. Restrictions on the BFRs would ban some of the most effective flame retardants available at a time in which politicians and firefighters were requesting increased levels of flame retardants for plastics in certain electrical and electronics applications. The ban on PBB would not affect the plastics market; PBDE, however, was still a widely used flame retardant in electrical plastics. The Commission was concerned about landfilling, incinerating, and recycling plastics containing BFRs because the end product could contain brominated dibenzofurans and brominated dibenzo-p-dioxins, which may be toxic. Separating out all plastics containing BFRs would present an additional cost to waste management because some of the plastics were fully recyclable and others, which contained brominated epoxy oligomer, had distinct advantages in terms of recyclability (Mapleston, 2000).

France.—Elf Atochem SA continued to switch from producing bromide derivatives to fine chemicals at its Port-de-Bouc plant in southeast France. The complex included a 12,000-t/yr bromine plant that supplied the downstream units. The company invested $12.8 million in the plant to produce alkyl bromides and dibromide, as well as ultrapure hydrobromic acid. Autofina completed a new 1,200-t/yr bromo-acids and bromo-esters plant. Albemarle operated a bromine derivatives facility at Thann and a flame retardants plant at Port-de-Bouc. Most of the production of brominated intermediates was sold to the pharmaceutical industry (Industrial Minerals, 2000d).

India.—Tamil Nadu Salt Corp. Ltd. planned a bromine plant

Digitized by Google

at the Valinokkam complex. The bromine would be a byproduct of salt production (Businessline, 1999, India—Tamil Nadu Salt Corp. to expand Valinokkam plant, accessed April 28, 2000, at URL http://www.proquest.umi.com).

Israel.—The production of bromine and potash began in 1931 at Kalia. The soluble minerals existed mainly as bromine and chloride anions and magnesium, potassium, and sodium cations. Bromine had been produced as a byproduct from waste bitterns associated with potash production from the Dead Sea since 1957 by DSB. After potash was removed in solar ponds, the waste bitterns were processed with chlorine to recover bromine. The brine contained 14,000 parts per million of bromine. The bromine-free bitterns were then processed to recover magnesium (Chemical Business Newsbase, 1999a).

In 1985, the Israeli Government began efforts to sell a share of Israeli Chemical Co. Ltd. (ICL) to offset an investment program. ICL was a group of chemical and mineral industrial companies, with commercial and marketing services, research institutes, and technical facilities. Israel Corp. bought an additional 17% stake in March 1997, which brought its total share of ICL to 41.9%. In 1997, the Israeli Government announced its decision to sell off its 31.5% stake of ICL valued at $441 million; the sale required the approval of the finance committee of the Israeli Parliament. In 1999, Potash Corp. of Saskatchewan planned to purchase as much as 30% of ICL.

DSB was a major producer of bromine and bromine compounds. The company was 89% owned by ICL. DSB, in turn, owned a number of subsidiaries. ICL made an offer to purchase the remaining 11% of DSB for $60 million (Chemical Market Reporter, 2000f). DSB had bromine manufacturing facilities at the Sdom plant and organic and inorganic bromine compounds at Ramat Hovav, and Broomchemie BV operated its subsidiary in the Netherlands (Chemical Business Newsbase, 1999d).

Japan.—Tosoh Corp. was Japan's only producer of bromine and hydrobromic acid used in the manufacture of dyes, flame retardants, pharmaceuticals, and photosensitive materials (Tosoh Corp., [undated], Bromines & flame retardants, accessed January 7, 2000, at URL http://www.tosoh.com/EnglishHomePage/tcdiv/tcdinbro.htm).

Jordan.—Jordan Bromine Co. Ltd., a joint venture between Arab Potash Co. (APC), its subsidiary Jordan Dead Sea Industries Co. (JODICO), and Albemarle Holdings Co. Ltd. of the United States, was incorporated in Jordan on January 11, 1999. APC had since purchased JODICO's shares in the joint venture resulting in a 50-50 joint venture between APC and Albemarle Holdings. A $150 million bromine complex in Safi included a 50,000-t/yr bromine plant, a 40,000-t/yr calcium bromide plant, and a 12,500-t/yr initial capacity TBBPA plant expandable to 37,500-t/yr. The plant would produce bromine for the merchant market and derivatives facilities, including inorganic bromides for oilfield completion fluids and TBBPA as a flame retardant, primarily for marketing in Europe and Asia (Kendall, 2000). Agra Monenco Inc. of Canada was awarded a contract to perform engineering, procurement, and construction management (Industrial Minerals, 2000a). Jordan Bromine obtained a loan from the European Investment Bank for the project.

Ukraine.—JSC Brom of Krasnoperekopsk, located at the Sivash Gulf on the Sea of Azov in Crimea, was reported to have 52,000 t/yr of bromine capacity (Industrial Minerals, 1998).

United Kingdom.—Production of bromine increased during 1999. Albemarle UK Ltd., a subsidiary of Albemarle, announced the acquisition of the Teesport operation of Hodgson Specialty Chemical Division of BTP plc for approximately $14 million. The Teesport facility was completed in 1991 and served as a custom manufacturing and oilfield chemicals plant. The addition of products that Teesport produced would complement Albemarle's clear completion fluids, amines, and chemicals to the oilfield services industry.

After bidding against Rhodia affiliate International Speciality Phosphates Group (ISPG) for Albright & Wilson (A&W), a maker of nonhalogenated flame retardants, Albemarle U.K. Holdings Ltd. sold its remaining shares (11%) of A&W stock to ISPG, a wholly owned subsidiary of Donau Chemie AG (Chemical & Engineering News, 1999a).

Current Research and Technology

Albemarle continued to improve its vacuum bromine recovery process that initially started up in June 1984, with the installation of a second generation vacuum bromine tower at its Magnolia facility in September 1998 and with the addition of a new bromine production facility in Union County, AR, in July 2000. Albemarle had three facilities in south Arkansas utilizing this patented two-stage vacuum bromine recovery technology consisting of a vacuum streamingout tower and a secondary steam recovery flash chamber. This highly efficient continuous recovery process made Albemarle globally more competitive by reducing bromine production costs and increasing tower capacity from that of prior technology.

Many biologically active agents were derivatives of natural products. A research team specializing in organic synthesis devised a new way to create large combinatorial libraries of such compounds. The new technique, developed by K.C. Nicolaou and coworkers at the Scripps Research Institute and the University of California was unique. A prenylated phenol group was immobilized on a polystyrene-based selenyl bromide derivative resin. The resin would be available commercially from Aldrich Chemical Co., Inc., Milwaukee, WI (Borman, 2000).

A research team at the National Center for Scientific Research of the University of Paris-South and Agfa Gervaert Group in Mortsel, Belgium, used a silver bromide dopant to improve the performance of photosensitive silver halide emulsions used to make photographic films. During the conventional photographic process, photons falling on silver halide microcrystals cause the halide ions to generate pairs of electrons and positive holes. The silver ions capture the electrons and the resulting neutral silver atoms group into clusters of metallic silver that form the latent image. This image was then developed into a visible image. This theoretical limit is one silver atom per absorbed photon. With the new dopant, formate ions produce carbon dioxide radicals that transfer energy to silver cations. The overall process is known as photo-induced bielectronic transfer because two electrons are generated. The bielectronic nanosilver halide system leads to the highest light efficiencies ever measured. All the light energy is used to produce the latent image without fogging the film (Chemical & Engineering News, 2000).

Researchers at Eastman Kodak in Rochester, NY, and at Arizona State University developed a photosensitization

Digitized by Google

process that could double the speed of photographic materials. In the Kodak process, an additional electron donor molecule reacts with the oxidized dye forming a radical cation. This cation undergoes irreversible fragmentation to produce a radical that donates a second electron to the silver halide. The increase in sensitivity of silver halide allows more freedom in designing photographic systems (Freemantle, 2000).

A team that included specialists in environmental sciences, metallurgical processing, mining, water treatment, and worker health studied extraction technologies at the McDonald gold project near Lincoln, MT. Bromine/sodium bromide was one of five alternative technologies studied to process the gold ore. Using the bromine/sodium bromide process required fewer daily truck shipments than the other four processes studied. The chemical conditions required for gold leaching by the bromide lixiviants are strongly acidic (De Voto and McNulty, 2000).

In quantum mechanics, particles are described by spread-out wave functions, seemingly existing in many places at once. A computer made of quantum particles has a built-in parallelism, because quantum calculations can be performed on the particles coexisting states simultaneously. Materials used in nuclear magnetic resonance quantum computers include 2,3-dibromothiophene. When nuclei with spin are placed in a magnetic field, they align themselves either parallel or antiparalled to the field, with a slight excess in the parallel orientation. A pulse of electromagnetic radiation of the right frequency and duration will flip a nucleus. A quantum bit, or qubit, can be set up to exist in the 0 and 1 states at the same time. The first quantum computer of Cory and colleagues of the Massachusetts Institute of Technology consisted of two hydrogen qubits in the molecule 2,3-dibromothiophene (Wilson, 2000).

Outlook

Petroleum.—Demand for bromine as a gasoline additive has declined each year since the EPA issued regulations in the 1970s to reduce and eliminate lead in automotive gasoline. In 1979, the amount of bromine sold for this application reached a peak of 225 Mkg. The rapid decline to 141 Mkg in 1986 was a direct result of the limits on lead in leaded automotive gasoline. The European Community continued discussions to reduce lead levels in gasoline. Bromine in petroleum additives was expected to continue to decline over the long term. Federal laws enacted to encourage alternative forms of power in automotive engines are likely to have a depressive effect on bromine demand. The CAA requires mobile sources, such as cars and trucks, to use the most effective technology possible to control emissions. Electric cars were on the market in California. Newer prototypes of the fuel cell that burns gasoline can double the mileage and thereby decrease emissions by using unleaded gasoline.

Sanitary Preparations.—Bromine was used in indoor swimming pools, hot tubs, and whirlpools. The sanitary preparation field is an area where bromine is safer than its substitutes, because bromine has a higher biocidal activity level for the same amount of product. Growth areas are in the pulp and paper industry, cooling towers, and Government-regulated food-washing applications. Albemarle reported double-digit sales growth of brominated biocides as it replaced chlorine and other products in a variety of applications (McCoy, 1998).

Fire Retardants.—Bromine is a reactive flame retardant in that it enters into chemical reactions with the components of the systems in which it is used. In addition, bromine acts as a synergist with many other fire-retardant materials and so increases the effectiveness of the fire retardant. A new nonbrominated material, a precursor to polybenzoxazole (PBO), which is a polyhydroxyamide that upon heating is converted to PBO, could limit flammability. This could have a major negative effect upon the use of BFRs, especially in airplanes, prisons, submarines, and ships (Chemical & Engineering News, 1999b).

Other Uses.—Use of calcium, sodium, and zinc bromides in well-completion fluids decreased during the 1980s as the domestic petroleum industry suffered a severe recession. In 1997, however, the oil-services sector posted another strong performance. About 95% of calcium bromide produced was used as an oil and gas completion fluid. Oilfield chemicals used in drilling, completion and workover, and production operations remained significantly more profitable internationally than in the United States. With the cutback of petroleum supplies internationally and the rising cost of energy for automobiles and heating, usage is expected to increase as new domestic wells are drilled and existing wells are serviced to become more productive.

e/ Estimated. r/ Revised. -- Zero.

1/ Data are rounded to no more than three significant digits.

2/ Harmonized Tariff Schedule of the United States.

3/ Elemental bromine sold as such to nonproducers, including exports, or used by primary U.S. producers in preparing bromine compounds.

4/ U.S. Census Bureau.

5/ Export values are free alongside ship (f.a.s.).

6/ U.S. Census Bureau. Includes methyl bromine and ethylene dibromide.

7/ Data for these compounds are derived from HTSUS numbers 2903.30.0500, 2903.30.1500 (1996, 1997, 1998, and 1999), and 2903.30.1520 (2000) information.

8/ Import values are cost, insurance, and freight (c.i.f.).

9/ The respective data for "bromides/bromines and oxides" of ammonium, calcium, and zinc are combined and reported here; imports for 1996 included 568 thousand kilograms, and imports for 1997 included 83 thousand kilograms of zinc bromide.

10/ The Journal of Commerce Port Import/Export Reporting Service.

11/ Bromides of sodium or of potassium import data are usually reported by a mutual HTSUS number, 2827.51.0000.

Michigan, Dow Chemical Co.	Mason	Ludington 4/	do.	20
Total				349

1/ Actual production capacity is limited by brine availability.
2/ This represents the cumulative capacity of the two identified plant sites.
3/ Closed yearend 1999.
4/ Bromine produced at this plant is reprocessed in Arkansas.

TABLE 3
YEAREND 2000 PRICES FOR ELEMENTAL BROMINE AND SELECTED COMPOUNDS

Product	Value (cents) Per pound	Per kilogram
Bromine:		
Drums, truckloads, works 1/	123	271
Bulk, tank cars, works 1/	56-68	123-150
Bromochloromethane, drums, bulk, f.o.b. Magnolia, AR	127	280
Ethyl bromide, technical, 98%, drums, truckloads	127	280
Ethylene dibromide, drums, carloads	95	209
Hydrobromic acid, 48%, drums, carloads, truckloads, f.o.b.	56	123
Hydrogen bromide, anhydrous, cylinders, 2,500 pounds, truckloads	475	1,047
Methyl bromide, tank cars	77	170
Potassium bromate, granular, powdered, 200-pound drums, carloads, f.o.b. works	179	395
Potassium bromide, N.F., granular, drums, carloads, f.o.b. works	110-112	242-247
Sodium bromide, technical, truckloads	70	154

1/ Delivered prices for drums and bulk shipped west of the Rocky Mountains, 1 cent per pound higher. Bulk truck prices, 1 to 2 cents higher per pound for 30,000-pound minimum.

CADMIUM

By Jozef Plachy

Domestic survey data and tables were prepared by Jason T. Collins, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

In 2000, production of cadmium metal in the United States increased by nearly 60% compared with very low production in 1999; production of cadmium compounds, including cadmium sulfide, declined by more than 30% (tables 1, 2). Apparent consumption increased by nearly 9%, but, for the fifth consecutive year, exceeded production (tables 1, 3). The difference was made up by imports and sales from the National Defense Stockpile, operated by the Department of Defense. After years of consecutive decline, the price for cadmium metal registered a modest increase in 2000.

In the United States, two companies, one in Illinois and another in Tennessee, produced primary cadmium as a byproduct of the smelting and refining of zinc concentrates in 2000. A third company, in Pennsylvania, recovered cadmium from scrap, mainly from spent nickel-cadmium (Ni-Cd) batteries. In 2000, the value of cadmium produced was calculated to be about $670,000. Although definitive consumption data do not exist, the International Cadmium Association (ICdA) has made the following estimates of cadmium consumption for various end uses in 2000: batteries, 75%; pigments, 12%; coatings and plating, 8%; stabilizers for plastics and similar synthetic products, 4%; and nonferrous alloys and other uses, 1% (Hugh Morrow, President, International Cadmium Association, oral commun., 2001).

In 2000, as in most years, the United States was a net importer of cadmium metal. The major source of U.S. imports was Belgium, accounting for about 23% of all imports, followed by Mexico and Australia, with 20% and 18%, respectively (table 6). Cadmium compounds and pigments were subject to import duties, but unwrought and powdered metal, as well as waste and scrap, entered duty free in all but a few cases. Cadmium, in all forms, from North American Free Trade Association member nations (Canada and Mexico) entered the United States duty free. As in 1999, the United States was a net exporter of cadmium sulfide, most of which was exported to China (84%), followed by the Philippines (8%) and Hong Kong (5%) (table 5). Trade data for other cadmium compounds were not available.

Cadmium was refined in 28 countries in 2000 (table 7). The six largest producers, in decreasing order, were Japan, China, the United States, Belgium, Canada, and Mexico. These countries accounted for more than one-half of world production; the United States accounted for nearly 10%. Identified world cadmium resources at yearend 1999 were estimated by the U.S. Geological Survey (USGS) to be 6 million metric tons (Mt), a figure based on zinc resources typically containing about 0.3% cadmium. The world reserve base was estimated to be 1.2 Mt, and reserves were 600,000 metric tons (t).

Legislation and Government Programs

During the last decade, regulatory pressure to reduce or even eliminate the use of cadmium, a metal which is toxic in certain forms and concentrations, has gained momentum, mainly in the European Union (EU), and some other developed countries as well. In the United States, many Federal and State agencies regulate the cadmium content of air, water (including bottled water), pesticides, color and food additives, waste, etc. In 1999, the U.S. Environmental Protection Agency (EPA) created a draft list of persistent, bioaccumulative, and toxic (PBT) pollutants. Since its publication, the PBT list continues to be controversial not only in the cadmium industry but also in the base metal industry since all nonferrous metallic elements are inherently persistent but not necessary bioavailable.

Cadmium is 1 of 11 metals among 53 chemicals on the draft PBT list targeted by the EPA for a 50% reduction by 2005. The ICdA objected to the inclusion of any metal, particularly cadmium, on the PBT list. One of the reasons for its objection was that no distinction was made between various cadmium compounds and cadmium metal itself. According to ICdA, it is not possible to give a single rating for cadmium and all of its compounds because of their widely varying solubilities and bioavailabilities. Highly soluble and bioavailable cadmium chloride and cadmium ions, for example, will have a much

Cadmium in the 20th Century

Germany produced the first commercial cadmium metal at the end of 19th century and was the most important producer until the outbreak of World War I. Production in the United States began in 1907 when the Grasselli Chemical Co. of Cleveland, OH, recovered 6 metric tons of cadmium metal as byproduct of zinc smelting. As imports from Germany were curtailed during World War I, domestic production rapidly increased, and by 1917 the United States became the world's leading producer of cadmium. Increased production was spurred by the development of the cadmium electroplating process in 1919 to coat mainly iron and steel.

By the 1940s, electroplating represented about three-fourths of cadmium consumption. Production and consumption of cadmium in the United States peaked in 1969, at 5,700 tons and 6,800 tons, respectively. Since then, both production and consumption declined because of environmental concerns due to toxicity of certain forms of cadmium. During the second half of the 20th century, the primary use of cadmium was for plates in batteries. By 2000, about three-fourths of the cadmium consumption was for batteries and the remaining one-fourth is used for pigments, coatings and plating, and as stabilizers for plastics.

Digitized by Google

different risk than cadmium metal, cadmium oxide, cadmium sulfide, and other insoluble compounds. Therefore, ICdA claims that the PBT rating for cadmium should recognize differences between the various forms of cadmium, their relative bioavailability, and thus their relative effects on human health and the environment. In addition, the draft PBT list failed to recognize that naturally occurring metallic elements are inherently persistent, but that such persistence results in less not more adverse environmental and human health effects. It is the bioavailable amounts of cadmium, according to ICdA, which are likely to lead to adverse health effects not the persistent amounts. During 2000, the opposition to the draft PBT list from various segments of industry, government, and academia continued to grow. Representatives of over 55 industry trade associations became signatories to a letter to EPA requesting a review of scientific documentation on which the list was based by its Science Advisory Board and seeking to defer inclusion of all metals in PBT programs until completion of that review. The trade associations assert that metals and inorganic metal compounds should be assessed under different criteria than synthetic organic chemicals for which the PBT methodology was first developed. The U.S. House of Representatives Committee on Science supported the industry by strongly encouraging EPA to review, as soon as possible, the scientific soundness of the methodology used in creating the PBT list (ILZRO Environmental Update, 2000b).

On another issue involving cadmium, the EPA decided to amend the existing Clean Water Act of 1995. The act requires the EPA to develop and, as warranted, revise water quality criteria so that its standards accurately reflect the latest scientific knowledge. The act also requires that water quality criteria be based solely on water data and scientific judgments; it does not consider economic impacts or the technological feasibility of meeting the criteria in ambient water. The latest revision involving cadmium was introduced on October 29, 1999, when EPA published the 2000 "Update of Ambient Water Quality Criteria for Cadmium" in the Federal Register. With this publication, the EPA made available to the public all references identified by a recent literature review and asked the public to submit any additional pertinent data or scientific views that would be useful in revising the aquatic life criteria for cadmium. The deadline for comments was October 17, 2000. After a careful review and incorporation of comments, an update of the Clean Water Act will be published in 2001 (U.S. Environmental Protection Agency, August 17, 2000, Notice of availability of draft aquatic life criteria document for cadmium, accessed November 25, 2000, at URL http://www.epa.gov/fedrgstr/EPA-WATER/2000/August/Day-17/w20972.htm). Most of the comments during the review period urged the EPA not to proceed with the cadmium update until the Biotic Ligand Model for cadmium was developed by the EPA which is considered a scientifically appropriate model to assess the toxicity of metals in aquatic environments. The model would integrate the physicochemical properties of the site-specific aquatic system, including pH, dissolved organic content, hardness, chloride content and alkalinity, with the biological component being protected. Consequently, the model would predict the bioavailability and toxicity of metals far more accurately than current methodologies. In many cases, this will result in more realistic criteria than those currently existing due to the incorporation of additional modifying factors (ILZRO Environmental Update, 2000d).

Because spent batteries are one of many sources of heavy metals emissions when incinerated or disposed of in landfills, certain European countries have adopted individual environmental standards on batteries containing cadmium, lead, and mercury. To avoid trade barriers created by disparities in such restrictions, the European Commission (EC) in 1991 unified these individual measures into Directive 91/157/EEC, which is binding for all EU member countries. The latest one, EU Directive 2000/60/EC on water, recommends phasing out the use of 32 chemicals over the next 20 years. The ban on Ni-Cd batteries is to start in 2008. If approved by the European Parliament, this directive will require all EU member countries to phase out the discharge of these hazardous chemicals into aquatic environments. Similar to the EPA, the Commission identified 11 of the chemicals for inclusion on a priority list of chemicals that they consider to be toxic, persistent, and liable to be bioaccumulate in the environment—the PBT list. Chemicals on this list, which includes cadmium, will be the first to be addressed by the Commission for possible phase out (ILZRO Environmental Update, 2001). In opposition to such a ban, the battery industry has proposed an EU-wide used battery collection scheme that would ensure recycling of at least 75% of Ni-Cd batteries possibly by 2004. ICdA argued that if the recycling goal is not achieved, cadmium could still be banned in time for the proposed deadline (The Lycos Network, August 3, 1999, Cadmium industry makes last charge against battery ban, accessed March 7, 2001, at URL http://ens.lycos.com/ens/aug99/1999L-08-03-02.html). In its November 2000 Organization for Economic Cooperation and Development (OECD) joint meeting of the Chemicals Committee and the Working Party on Chemicals, however, the EC representatives blocked any attempt to adopt an OECD-wide Ni-Cd battery recycling label (ILZRO Environmental Update, 2000c). In addition to the battery and cadmium industries, manufacturing companies and organizations also expressed reservation about EC's efforts to ban cadmium-containing devices. The American Electronics Association and the Electronics Industries Alliance expressed concern that the ban was being proposed without any analysis of the environmental impacts of replacement materials and processes. The Electric Vehicle Association of Great Britain also opposed the proposed ban, which the association claims could set back the cause of electric vehicles in the EU by 20 years (Advanced Battery Technology, 2000).

In 1991, the U.S. Congress authorized the disposal of the entire stockpile of 2,872 t of cadmium from the National Defense Stockpile. In 2000, the Defense Logistics Agency, which manages the stockpile, sold 319 t of cadmium metal, leaving 807 t still to be sold.

Production

The most common cadmium mineral is greenockite, which is almost always associated with the zinc ore mineral, sphalerite. The average ratio between contained zinc and cadmium in sphalerite is about 400:1 or 0.25%. At least 80% of cadmium output worldwide is estimated to be a byproduct of primary zinc production. The remaining 20% is obtained from secondary sources, such as baghouse dust and the recycling of cadmium products, and from the production of other primary metals. Because of depressed cadmium prices in recent years, the processing of many wastes to recover cadmium has not been economically viable. Thus, cadmium is usually extracted to

Digitized by Google

remove it from zinc, lead, or copper production or to recycle cadmium-containing products.

In the United States, only two companies produced primary cadmium during 2000—Big River Zinc Corp., Sauget, IL, and Pasminco Ltd., Clarksville, TN. Both companies used an electrolytic process and recovered the cadmium as a byproduct during the roasting and leaching of zinc concentrate. After removing various impurities, cadmium can be processed to final form by either refining or electrowinning.

The Sauget operation, owned by Korea Zinc Co. Ltd., can produce up to 1,400 metric tons per year (t/yr) of cadmium metal and oxide. About 80% of its concentrate feed was supplied by mines in Missouri and Tennessee, and the remaining 20% was imported, mainly from Canada, Mexico, and Peru (Mining Journal, 1999). The cadmium content of zinc sulfide concentrate is usually between 0.1% and 0.8%. The concentrate is heated in fluidized bed roasters to produce an impure zinc oxide (calcine) suitable for acid leaching. Between 60% and 85% of the calcine, which contains cadmium and other impurities, is volatized with the sulfur dioxide gas generated during the roasting process. Calcine and fume are separated from the gas and collected in waste heat boilers, cyclones, and electrostatic precipitators. The collected calcine dust is combined with the unvolatilized portion of the calcine and dissolved in sulfuric acid at a leaching plant. Generally, manganese dioxide is added to the leaching tank to remove iron and significant amounts of other impurities. These insoluble residues are sold to other smelters for further processing as iron cake. The leachate is sent to a series of cold and hot purification tanks where cadmium and other remaining undesirable metals are removed from the solution. After the first stage of zinc sulfate purification, discharged impurities form a copper cake, which, like the previously captured leach residues, are sold for processing. The bulk of cadmium is precipitated in the second stage of purification, and the remainder is precipitated in a third stage. The cadmium precipitate is filtered and forms a cake containing about 12% cadmium, 25% zinc, and small amounts of other impurities. The cake is then redissolved in sulfuric acid. After two additional acid treatments, a cadmium sponge is produced, which is dissolved in another sulfuric acid bath, and the solution, if sufficiently pure, is passed into electrolytic cells where the cadmium is deposited on cathodes. The resulting more than 99.99%-pure cadmium metal is melted and cast into 50-millimeter (mm)-diameter ball anodes or 250-mm-long sticks or oxidized in a controlled atmosphere to produce cadmium oxide powder. Higher purity cadmium for special purposes, such as for semiconductors, can be produced by vacuum distillation (U.S. Environmental Protection Agency, 1987).

In 1999, Pasminco Ltd. of Australia acquired Savage Zinc Inc. and its parent company, Savage Resources Ltd., also from Australia (Pasminco Ltd., [undated], Welcome to Pasminco, accessed June 1, 2000, at URL http://www.pasminco.com.au). The acquisition extended Pasminco's zinc distribution network into the U.S. market. After the acquisition, Pasminco stated that a plan to triple zinc production capacity at its Clarksville smelter would be postponed (Financial Express, [undated], Pasminco's U.S. smelter expansion plan put on hold, accessed May 3, 2000, at URL http://www.financialexpress.com/fe/daily/19990904/fco04016p.html). In 2000, most concentrate for the Clarksville smelter was supplied by local mines owned by Pasminco and ASARCO Incorporated. When more favorable market conditions develop, Pasminco may expand the smelter. If the capacity of the smelter is increased, domestic production will need to be augmented by imported zinc concentrate, most likely from the newly opened Century Mine in Australia. Increased zinc production could affect cadmium production at the Clarksville smelter, which at present can produce up to 500 t/yr.

The amount of cadmium that is recycled is difficult to estimate for a number of reasons. For example, cadmium from baghouse dust generated at lead and copper smelters enters the primary cadmium production circuit at zinc refining operations and may or may not be included in reported production statistics for primary cadmium metal. Although the reported amount of cadmium produced from the recycling of Ni-Cd batteries is fairly accurate, there are no firm data on the amounts of cadmium recovered from other sources such as electric arc furnace dust, electroplating wastes, filter cakes, sludges, and other cadmium-containing materials. Electric furnace dust, which contains about 0.05% cadmium, is recovered only because it is mandated by environmental regulations; cadmium prices were so depressed in 2000 that the processing of furnace dust for any other purpose was not economically feasible.

In 1995, International Metals Reclamation Co. Inc. (INMETCO), a subsidiary of the International Nickel Co., began reclaiming cadmium from spent batteries at its Ellwood City plant northwest of Pittsburgh, PA. The $5 million high-temperature metal recovery plant addition, built by Davy International Ltd., was the first facility of its kind in the world. It is capable of processing more than 2,500 t/yr of spent Ni-Cd batteries. Cadmium recycling at the facility thus far has been practical only for Ni-Cd batteries, some alloys, and dust from electric arc furnaces. The most difficult aspect of Ni-Cd battery recycling is the collection of spent batteries. Large industrial batteries, containing 20% of the cadmium used for batteries, are easy to collect and are recycled at a rate of about 80%. The remaining 80% of the cadmium used in batteries goes into small consumer Ni-Cd cells and batteries, which for the most part are usually discarded with municipal solid wastes. Therefore, voluntary industry-sponsored collection programs and Government agencies are devising ways to improve the collection of these small batteries. Economies of scale are very important, and the larger a recycling operation, the lower its unit cost is likely to be. Several different collection programs have been developed by INMETCO to meet the needs of battery manufacturers and the numerous consumers, firms, organizations, and agencies that use many diverse products, such as power tools, cordless phones, and personal computers (Industrial Heating, 2000). Rechargeable Battery Recycling Corp. (RBRC) operates the "Charge Up to Recycle!" program, established in 1995, which has organized a multifaceted collection program to collect rechargeable consumer batteries. The RBRC generates revenue for the program by licensing its seal of approval to individual companies involved in the manufacturing, importation, and distribution of rechargeable batteries or battery-operated products. The "Charge Up to Recycle!" program contains several key elements that are specified both in EPA regulations (40 CFR part 273), Federal law (The Mercury-Containing and Rechargeable Battery Management Act of 1996), and in various State laws. These elements include uniform battery labeling, removability from appliances, national network of collection systems, regulatory

Digitized by Google

relief to facilitate battery collection, and widespread publicity to encourage public participation. For that purpose, RBRC has undertaken an extensive public education campaign and has established several recycling programs in the United States, such as the Retail Recycling Plan (8,500 participants), the Community Recycling Plan (300 enlisted), and the Business & Public Agency Recycling Plan (1,000 enrolled) (Hugh Morrow, President, International Cadmium Association, written commun., 2001). The RBRC program has about 30,000 collection sites in the United States and Canada, including many at the outlets of major participating retailers. Most of the industrial wet Ni-Cd batteries were recycled through collection programs in which producers of industrial batteries collect and send their spent batteries to INMETCO. A smaller portion of industrial batteries was collected and shipped by various environmental organizations (Bleakney, 1998).

The process of cadmium recovery from industrial and consumer sealed batteries, both of which contain about 15% cadmium by weight, differs only in the manner of battery preparation. Processing of industrial batteries consists of draining the sodium hydroxide electrolyte, cutting the tops off the batteries, and separating the nickel and cadmium plates. Small batteries must be handsorted because only newer batteries are color coded and very few of them carry bar codes, making optical scanning and other automated sorting very difficult.

The cadmium plates from the industrial batteries and the small batteries, from which the plastic casing has been removed in INMETCO's patented thermal oxidizer, are charged into a cadmium recovery furnace. In the furnace, carbon is added as a reductant. The charge is heated and the cadmium is distilled, then collected in a water bath. The final products, called Cadmet shot, are small flattened discs, 4 to 6 mm in diameter, to facilitate handling and to reduce erratic rolling, and have a purity of greater than 99.95% cadmium, some as high as 99.999% cadmium. Cadmet is drummed, weighted, assayed, and shipped to Ni-Cd battery manufacturers for reuse in new batteries, but may also be used in the manufacture of corrosion-resistant coatings or in the manufacture of cadmium-containing stabilizers, alloys or pigments.

In addition to the pyrometallurgical process for recycling cadmium, in which cadmium vapor is collected and then solidified by condensation or oxidation, there are hydrometallurgical cadmium recycling processes as well. In these wet chemical processes, batteries are dissolved in strong acids, then subjected to selective precipitation or ion exchange reactions to separate cadmium compounds from nickel and iron compounds.

Although secondary production has been increasing at about 6% per year and most likely will increase even faster in the future, worldwide primary production will remain basically unchanged for the next few years. Any future increases in domestic production of virgin cadmium will likely come from the Crandon/Rhinelander zinc-copper deposit in northeastern Wisconsin. Its development will depend on the zinc market and on Nicolet Minerals Co., a wholly owned subsidiary of Rio Algom Mining Corp., acquiring some remaining permits from the Wisconsin State Government. Nicolet's proposal of a future mine near the headwaters of the Wolf River, however, is opposed by those who feared the pollution of underground water and altered water levels of nearby lakes caused by pumping of water to keep the shafts dry. The deposit contains an estimated 62 Mt of ore grading 5.6% zinc, 1.1% copper, and 0.01% to 0.23% cadmium (Skillings' Mining Review, 1978). Sphalerite from one particular stratigraphic sequence, the Skunk Lake unit, consistently had the highest cadmium values, averaging 0.09% cadmium (Lambe and Rowe, 1987). Pyrite is ubiquitous throughout most of the deposit. Development of the deposit would include the building of a 2-Mt-capacity mill with an annual production of between 200,000 t and 300,000 t of zinc concentrate and about 20,000 t combined copper-lead concentrate (Metal Bulletin, 1996).

Environmental Issues

Despite being toxic in high concentrations of soluble or respirable forms, dermal contact with cadmium metal results in negligible absorption. However, prolonged exposure to high concentrations of the respirable and soluble forms of cadmium is known to have toxic health effects and adverse environmental impacts. Inhaled cadmium fumes or fine dust are much more readily absorbed than ingested cadmium. Repeated exposure to excessive levels of dust or fumes can have irreversible effects on kidneys and on lungs, producing shortness of breath and emphysema. Because of these potential adverse effects, occupational exposure to cadmium in the United States is regulated by the Occupational Safety and Health Administration (OSHA). OSHA's permissible limit for cadmium exposure through inhalation is 5 micrograms per cubic meter of air breathed (Golden Artist Colors, [undated], Will cadmium always be on the palette?, accessed March 7, 2001, at URL http://www.goldenacrylics.com/cadmiums.htm). Similarly, strict air and water emission limits on cadmium as well as land disposal restrictions on the metal are in effect in the United States and other countries. In the United States, any cadmium-containing waste that leaches more than 1 milligram per liter is considered hazardous waste. Any discharge of cadmium chemicals above a specific threshold level into navigable waters is subject to reporting requirements. The Reference Dose for cadmium in drinking water is 0.0005 milligrams per kilogram per day (mg/kg/d) and in food is 0.001 mg/kg/d (U.S. Environmental Protection Agency, [undated], Cadmium and compounds, accessed March 7, 2001, at URL http://epa.gov/ttnuatw1/hlthef/cadmium.html).

The four main environmental and human health concerns involved with Ni-Cd batteries are occupational exposure, manufacturing emissions and wastes, product use, and product disposal. Because most of the environmental and health problems involved in the production of Ni-Cd batteries can easily be controlled, recent regulations have focused on disposal options. Basically, only four disposal options are available—composting, incineration, landfilling, and recycling. The first two options are not practical; landfilling was the most frequently used alternative and recycling was the one most preferred by the industry and environmentalists. Because most cadmium is produced as a byproduct, mainly of zinc production, restrictions on the use of cadmium in batteries could increase the amount of unprocessed cadmium that is disposed in landfills by zinc producers. Therefore, an effective collection and recycling system for spent batteries would probably protect the environment more than a ban on cadmium in batteries.

Consumption

The USGS does not collect consumption data on either

Digitized by Google

cadmium metal or cadmium compounds. Apparent consumption of cadmium metal in the United States is calculated by the USGS from production, trade, and stock changes. Apparent consumption in 2000 increased by nearly 9%, compared with that of 1999. Estimated consumption of cadmium by end use in 2000 was as follows: batteries, 75%; pigments, 12%; coatings and plating, 8%; stabilizers for plastics and similar synthetic products, 4%; and nonferrous alloys and other uses, 1%.

Cadmium metal has a low melting temperature, good electrical conductivity, excellent corrosion resistance in alkaline and saline environments, and the ability to improve the mechanical properties of other metals. Therefore, cadmium metal is commercially used mainly as a corrosion-resistant coating on steel, aluminum, and other nonferrous metals, especially where low friction or low electrical resistivity is needed. Cadmium metal is also added to some nonferrous alloys to improve properties such as strength, hardness, wear resistance, castability, and electrochemical behavior. All cadmium compounds are made from cadmium metal and are primarily used in batteries, pigments, ultraviolet light and weathering stabilizers, and semiconductor applications.

Although cadmium consumption for batteries has been growing steadily for more than 15 years, other cadmium markets, such as pigments, stabilizers, coatings, and alloys, are regarded as mature because they are not expected to grow; in fact, some of the markets have already started to decline. Consumption of cadmium for these dispersible and dissipative applications probably will continue to decline because of increasingly stringent environmental regulations, concerns of manufacturers about long-term liability, and the development of less toxic substitutes. Use of organic cadmium compounds as stabilizers in polyvinyl chloride (PVC) continues to decline since the barium-cadmium stabilizers used in the past can now readily be substituted by barium-zinc, calcium-zinc, or organo-tin stabilizers. Consumption patterns of cadmium compounds varied significantly among countries because of differences in environmental regulations, industrial development, natural resources, and trading patterns. In the United States, Ni-Cd batteries provided the power for three-fourths of the most common portable products, such as cordless telephones, portable household appliances, power tools, battery-powered toys and hobbies, and emergency and remote area power. It is estimated that there are more than 450 million cordless electronic products in the United States.

The consumption of cadmium in batteries could receive a boost from manufacturers of hybrid electric vehicles and providers of telecommunications in remote areas. Although preference for Ni-Cd batteries over other kinds of batteries in hybrid vehicles has not been indisputably established due to environmental restrictions, application as a power source for telecommunications in remote areas holds considerable promise for future cadmium use. Compared to traditional valve-regulated lead acid batteries, the Ni-Cd batteries have longer life, are more reliable, require lower maintenance, have unlimited shelf life, and have the lowest life cycle cost. Replacement and new production of these batteries for telecommunications could translate into an annual requirement of about 2,000 t, or over 10% of the current world's production (Vigerstol, 1998). One of the most promising applications from the cadmium industry's perspective is the use of cadmium telluride solar cells to convert sunlight into electricity and the use of Ni-Cd batteries to store that electrical energy for remote power systems. Consumption for this application could be as high as 5,000 t/yr (Hugh Morrow, President, International Cadmium Association, oral commun., 2001).

A wide variety of cadmium sulfide-based compounds are used as yellow, orange, and red pigments for plastics, glasses, ceramics, enamels, and artists' colors. Organic alternatives still cannot match many of the popular properties of cadmium pigments, especially color brightness, opacity, and processability. One of the more promising noncadmium colorants is a cerium sulfide developed in France (American Metal Market, 1997). Cadmium pigments are particularly well suited for applications requiring high temperature or high-pressure processing or applications where other pigments will readily degrade. Cadmium carboxylates, such as laurate and stearate, are used as ultraviolet light and weathering stabilizers for PVC. The finished PVC product usually contains no more than 0.2% cadmium. The cadmium is locked into the polymer matrix and has extremely low leachability (Donelly, 1996).

Prices

As the byproduct of other metals production, cadmium is not subject to the normal supply-demand dynamics of most metals. The inelastic supply-demand situation associated with byproduct commodities invariably leads to volatile pricing, and such has been the case for cadmium over the past 20 to 30 years. Until the late 1980s, cadmium was used mainly in pigments and alloys. After the Ni-Cd battery was developed, the battery market expanded by 20% per year, and the price of cadmium increased to $9.10 per pound by March 1988. With the exception of 1995, the 1990s were marked by a steady decline in cadmium prices due to tightening regulatory controls and thus reduced consumption in some traditional cadmium markets such as pigments, stabilizers, and coatings. In addition, recycling of cadmium batteries has also led to the availability of secondary cadmium. Cadmium prices remained at historically low levels in 2000. As world supply tightened toward the end of year, however, prices for high purity cadmium (99.99%) began to inch upward. Reduced primary production, offsetting increased secondary cadmium output, and continued moderate demand in spite of regulatory concerns led to a balanced world cadmium market in 2000. Despite increased supply, the price for cadmium in the United States began to increase at the end of 2000 (table 1).

Current Research and Technology

A relatively new process for secondary production of cadmium from recycled Ni-Cd batteries was developed in the past 5 years by a German firm, ACCUREC GmbH. The new process, know as Vacuum Thermal Recycling, is the first ultralow emission process that can be installed modularly with capacities of between 500 t/yr and 5,000 t/yr. The vacuum process has advantages because under vacuum all elements evaporate at a significantly lower temperature and the hermetic construction prevents contamination by escaped gases. A charge of about 500 kilograms of spent batteries is inserted in a quartz pipe that is vacuum-sealed and is heated to 100° C to 150° C. After all water has evaporated, the charge can be heated to the operating temperature of about 750° C. Following the inclusion of various additives, the cadmium oxide is reduced

and evaporated. The metal vapor is then water-cooled in a metal condenser, where it forms a metallic cadmium block (Wehye and Melber, 2000a).

In rare welcome news for the cadmium industry, a Princeton University study found that, under certain conditions, some organisms grow better when they contain cadmium. According to the study, cadmium joins a group of elements (such as selenium, nickel, tungsten, and iron) that can have either a toxic effect or perform an essential biological function, depending on environmental conditions. The enzymes that help interconversion of carbon dioxide, essential for respiration in animals and fixation of carbon dioxide during photosynthesis in plants, require a metal, which is usually zinc. However, under conditions where zinc is scarce, some marine organisms produce a cadmium-specific carbonic anhydrase. For example, the marine diatom *Thalassiosira weissflogii* produces a cadmium-specific carbonic anhydrase when it is starved of zinc and cannot make enough of the zinc-requiring carbonic anhydrase (ILZRO Environmental Update, 2000a).

A University of Arkansas research team has found a way to replace dimethylcadmium with cadmium oxide to form nanocrystals, which are used in applications such as special electronics and optoelectronic devices. Dimethylcadmium is a toxic chemical that is unstable at room temperature and explosive at higher temperatures. The researchers discovered that from a base of safer cadmium oxide they can make a variety of nanocrystals incorporating several different materials (Business Week, 2001a).

At the University of California at Berkeley, new forms of cadmium selenide crystals have been developed for use in the manufacture of solar panels. The new crystals facilitate electron flow and could boost efficiency to over 20%, compared to far more expensive existing solar cells (Business Week, 2001b).

Outlook

Historically low prices, limited growth in many mature cadmium markets, and pending environmental restrictions are factors that must be considered in forecasts for the cadmium industry. Zinc mining companies that produce cadmium as a byproduct, have begun to regard the metal as a cost rather than a credit. The cost of producing cadmium, which is difficult to determine apart from zinc, probably has exceeded the sale price in some cases. The immediate future of the cadmium industry rests largely with the Ni-Cd battery market, which is the only market that continues to grow, especially in certain sectors, such as power tools and telecommunication uses. Following declines in recent years, the coatings and pigments markets for cadmium have stabilized and are not expected to erode any further in the future. The stabilizers and alloys markets, however, are expected to diminish and eventually close due to substitution by cadmium-free products. However, several new applications, such as telecommunications, electric and hybrid electric vehicles, remote area storage systems, and solar cells could become significant cadmium markets.

The future of the cadmium market will be determined by the extent to which industry is able to fully implement the collection and recycling of cadmium products. The success of new cadmium recycling technologies is critical not only in battery markets, but also for other principal end-use products. Recycling of industrial Ni-Cd batteries, which retain nearly 100% of the market for emergency lighting, alarms, and power tools, and have a production rate that is growing by about 3% per year, has begun and is expanding. The rechargeable battery industry has been growing significantly in recent years and is expected to continue growing well into the 21st century. State and Federal mandates now require manufacturers and battery resellers (companies that use Ni-Cd batteries in their products) to recycle rechargeable batteries and prohibit commercial users from discarding them in municipal solid waste. Further increases in the recycling rate for rechargeable batteries will depend on the cooperation of consumers, which in turn will reflect the convenience of collection systems (Rechargeable Battery Recycling Corp., [undated], The non-profit company that recycles Ni-Cd rechargeable batteries, accessed April 25, 2000, at URL http://www.rbrc.org). According to a survey conducted by the RBRC, 95% of Americans own cordless electronic products, but just 16% recycle their power sources (American Metal Market, 1999). Because spent Ni-Cd batteries are 100% recyclable, battery collection and recycling systems that are economically viable as well as environmentally sound may be possible. Collection and recycling rates must continue to increase to reassure regulators and the general public that any human health or environmental risks associated with cadmium will be well managed. Improved recycling of Ni-Cd batteries is also necessary to forestall a ban on the use of cadmium in Europe. Recycling of cadmium products other than batteries, however, will be considerably more difficult. The proper disposal of discarded plastics, obsolete electronic parts, incinerator residues, and municipal sewer sludge—all of which often contain low levels of dispersed cadmium—remains a difficult problem. Moreover, even though increased cadmium recycling is environmentally desirable, it will have only a limited effect on the amount of cadmium in the environment: According to recent estimates, just 2% of cadmium present in the environment is attributable to all uses of the metal. Most of the cadmium released into the environment results from the burning of fossil fuels and from iron and steel production (Metal Bulletin, 1999).

U.S. collection and recycling programs for small rechargeable batteries are expected to expand further, and has now moved into Canada. The Portable Rechargeable Battery Association has helped to enlist the participation of county and municipal governments, hospitals, and fire departments. Spent Ni-Cd, nickel-metal hydride, lithium-ion, and small sealed lead-acid batteries are now all being collected under the program (Greg Broe, Portable Rechargeable Batteries Association, oral commun., 2001). According to the RBRC, about 1,700 t of rechargeable batteries was recycled in 2000. Assuming an average cadmium content of 15% per battery, more than 255 t of cadmium was recycled rather than discarded in landfills (Greg Broe, Portable Rechargeable Battery Association, oral commun., June 2001).

1/ This table gives unwrought production from ores, concentrates, flue dusts, and other materials of domestic and imported origin. Sources generally do not indicate if secondary metal (recovered from scrap) is included or not; where known, this has been indicated by a footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, Ware, the United Kingdom) and from Metal Statistics (published jointly by Metallgesellschaft AG, of Frankfurt am Main, Germany, and World Bureau of Metal Statistics). Cadmium is found in ores, concentrates, and/or flue dusts in several other countries, but these materials are exported for treatment elsewhere to recover cadmium metal; therefore, such output is not reported in this table to avoid double counting. This table includes data available through May 11, 2001.

2/ Reported figure.

3/ Excludes secondary production from recycled nickel-cadmium batteries.

4/ Less than 1/2 unit.

5/ Excludes significant production of cadmium oxide and cadmium contained in exported concentrates.

6/ Tsumeb Smelter closed in April 1998.

7/ Includes secondary.

CEMENT

By Hendrik G. van Oss

Domestic survey data and tables were prepared by Nicholas Muniz, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

As the binding agents in concrete and mortars, hydraulic cements are key construction materials. Hydraulic cements are those that can set and harden under water and are dominated by varieties that can be loosely grouped as portland cement and masonry cement. Only portland and masonry cements are covered in this report. In 2000, U.S. production of portland and masonry cements, combined, continued a multiyear trend of new annual records with a 2.2% increase to 87.8 million metric tons (Mt) (table 1). Output of clinker—the unground intermediate product of cement manufacture—increased by almost 3% to a new record of 78.1 Mt. The United States continued to rank third in the world in overall hydraulic cement output, behind China (about 36% of the world's total) and India; world output was about 1.6 billion metric tons (Gt).

Domestic consumption of cement again reached new record levels, but the growth in 2000 was significantly slower than annual rates over the period 1995-99 and reflected weakness in the overall U.S. economy. Apparent consumption of cement in 2000 (calculated as production plus imports minus exports minus the change in yearend stocks) rose only by 1.5% to 110.5 Mt; it had grown by 5.2% in 1999 (table 1). Cement consumption measured as sales to final domestic customers increased by 1.0% to 109.7 Mt (table 9); the growth rate was only one-fifth of that of the previous year. The large production shortfall in 2000, as in previous years, continued to be met by imports of cement and clinker but at a slightly lower level overall; it was the first decline since 1992. Exports, in contrast, rose in 2000 but remained an almost insignificant component of total cement commerce. Cement prices were virtually unchanged during the year. The total ex-factory value of annually reported cement sales to final domestic customers rose by 2.6% to $8.3 billion (table 1). If the unit value of the cement is applied to the larger, monthly-based sales tonnages in table 9, the total rises to $8.6 billion but is an increase of only 1.2%. By using typical cement-in-concrete mix ratios, the delivered value of concrete, excluding mortar, in the United States was estimated to be at least $37 billion in 2000.

Portland and masonry cements are based upon portland cement clinker, made up mostly of calcium silicates and manufactured by controlled high-temperature burning in a kiln of a measured blend of calcareous rocks (usually limestone) and, as needed, lesser quantities of siliceous, aluminous, and ferrous materials. The clinker is finely ground together with a small (generally about 5%) amount of calcium sulfate in the form of gypsum and/or anhydrite to make (straight) portland cement. Straight portland cement can be sold directly to concrete manufacturers or other customers, converted at the cement (or concrete) plant into a blended (portland) cement product of similar properties by adding other cementitious or pozzolanic (siliceous materials requiring added lime to become cementitious) extenders, or mixed with such plasticizing materials as ground limestone or lime to make masonry-type cements used in mortar. A full listing of cement varieties included within the portland cement designation as used in this report is given in table 16. Although included within the portland cement designation in this report, data showing blended cements separately from the other forms of portland cement are available within the monthly cement reviews of the

Cement in the 20th Century

In 1900, the hydraulic cement industry of the United States was less than a century old, and until that year, its output had been dominated by natural and pozzolanic cements. Portland cement had been manufactured domestically since only the early 1870s, and by 1900, its output of 1.46 million metric tons had just exceeded that of natural and pozzolanic cements (1.22 million tons, combined) for the first time. In 1900, hydraulic cement production was valued at $19.4 million. Cement was being manufactured at 114 plants, 50 of which produced portland cement. Total world cement production was probably only about 60 million tons, of which 44 million tons was in Europe. Cement consumption in the United States totaled 3.07 million tons in 1900, or about 24 kilograms per person. About 13% of the total cement consumed was imported, mostly from Europe. Most of the consumption was for concrete blocks and mortars.

In 2000, production of cement reached 87.8 million tons, valued at about $6.9 billion; about 95% of output was portland cement. Output was from 116 plants, most of which were owned by European-based multinational corporations. Consumption of cement totaled 109.7 million tons, or about 380 kilograms per person; the 22-million-ton production deficit was met by imports from around the world. The dramatic increase in production and consumption during the course of the century reflected increasing diversity of use of concrete in large office buildings, houses, roads, bridges, sewers, and dams. Except for major disruptions during the Great Depression and World War II, production had risen fairly continuously, reaching about 30 million tons by 1928 and again by 1947, surging through the 1950s onwards to about 78 million tons in 1973, fluctuating at lower levels over the period 1974-93, and resuming steady growth thereafter. World production in 2000 totaled about 1.6 billion tons, almost 60% of which was from Asia; China and India together contributed 40%.

Digitized by Google

U.S. Geological Survey (USGS) Mineral Industry Surveys series, starting with January 1998. Excluded from the portland and masonry categories and from this report are such hydraulic cement varieties as pure pozzolan cements [especially so-called slag cement, which is simply ground granulated blast furnace slag (GGBFS)] and aluminous cements. These cements contain no portland cement clinker and, cumulatively, make up only a small fraction of the U.S. cement market.

The bulk of this report incorporates data compiled from USGS annual questionnaires sent to individual cement and clinker manufacturing plants and associated distribution facilities and import terminals (some independent of U.S. cement manufacturers). For 2000, responses were received from 143 of 144 facilities canvassed, which included all producers, covering 100% of actual production and more than 99% of sales. For 1999, responses were received from 139 of 141 facilities canvassed, including all but 1 small producer, and covering more than 99% of total U.S. production and sales. Two tables (9 and 10) of this report are based on monthly shipment surveys of the cement-producing companies and importers, for which the response rate was 100% for both years. Trade data are from the U.S. Census Bureau. The world hydraulic cement production data (table 23) were derived from data collected by USGS country specialists from a variety of sources.

As in previous years, significant tonnage differences exist between the annual (survey) sales totals for portland cement listed in tables 1 and 11 through 16 and the larger monthly-survey-based totals listed in tables 9 and 10. The differences, amounting to 5.3 Mt in 1999 and 4.0 Mt in 2000, likely represent imported cement handled by certain terminals acting independently of the manufacturing plants; although incorporated within the monthly data set, some of these terminals' sales appear to be missing from the annual survey. Accordingly, the monthly data are believed to be the more complete measure of cement consumption. The equivalent discrepancy for masonry cement is insignificant, likely because little of this material is imported.

Where required to protect proprietary information, State data are combined within groupings or districts, generally corresponding to census districts or subsets thereof. To provide additional market information, some major cement-producing States have been subdivided along county lines; the county breakouts are given in table 2.

There were three significant ownership changes within the U.S. cement industry in 2000. In June, Australian-owned CSR America, Inc. (owner of Miami, FL, cement producer CSR Rinker Materials, Inc.) purchased Florida Crushed Stone Co., which operates a dry plant at Brooksville, FL. Two months later, Greek producer Titan Cement S.A. purchased the assets of Anglo American plc's subsidiary Tarmac America, Inc., thereby gaining full control of Roanoke Cement Co. in Virginia (in which Titan was already a joint-venture partner) and Pennsuco Cement Co. in Florida. Titan also owned Essex Cement Co., a New Jersey-based cement importer. By far the most important ownership transfer, however, took place at the end of September, when Cemex S.A. de C.V. of Mexico (CEMEX) announced its purchase of Southdown, Inc., the second largest U.S. cement producer and (hitherto) the largest U.S.-owned cement company. Prior to this purchase, CEMEX's only production facility in the United States was the Balcones Plant (formerly operated under the name Sunbelt Cement Co.) in Texas, and the company owned large import terminals in California and Arizona. With the purchase of Southdown, CEMEX gained control of a dozen more plants spread throughout the country—namely at Brooksville, FL; Charlevoix, MI; Clinchfield, GA; Demopolis, AL; Fairborn, OH; Knoxville, TN; Kosmosdale, KY; Lyons, CO; Odessa, TX; Pittsburgh, PA; Victorville, CA; and Wampum, PA—as well as a number of terminals. The Kosmosdale and Pittsburgh plants were joint ventures with Lone Star Industries, Inc. (25%).

Early in the year, Lafarge, the world's second largest cement producer, launched a well publicized hostile takeover bid for British company Blue Circle Industries, a major rival world and U.S. cement producer. Had it been successful, the merger would have made Lafarge the largest cement producer in the world and the United States. The bid failed when, in May, Blue Circle shareholders rejected Lafarge's bid.

Legislation and Government Programs

Economic Issues.—Government economic policies and programs affecting the cement industry chiefly are those affecting cement trade, interest rates, and public sector construction spending. In terms of trade, the major issue in 2000 remained that of antidumping tariffs against Japan and Mexico and a related voluntary restraint (import price) agreement with Venezuela that were imposed in the early 1990s following complaints in the late 1980s by a large coalition of U.S. producers. On March 6, 2000, the U.S. Department of Commerce (DOC) released its determination for the (eighth) review period covering August 1997 to July 1998; the dumping margin for the period was set at 45.84% (Southern Tier Cement Committee, 2000a). Pursuant to a World Trade Organization agreement, which became effective in 1995 and which required a sunset review after 5 years to determine the necessity of continued antidumping tariffs, a review was begun in mid-1999 of the antidumping remedies imposed on Japan, Mexico, and Venezuela. On June 27, 2000, the DOC issued the results of its part of the sunset review (as to whether dumping would continue or resume if tariffs were removed). The determination was that dumping would continue/resume at high margins by all three countries (Southern Tier Cement Committee, 2000b). The second investigation under the sunset review process was conducted by the U.S. International Trade Commission (ITC) and was to determine whether or not dumping, if continued or resumed, would cause injury to the U.S. cement industry. On October 5, the ITC concluded its investigation, determining, on a majority vote, that injury would occur if dumping resumed or continued by Japan and Mexico. Accordingly, the antidumping remedies against these two countries would be maintained for another 5 years. However, in a unanimous vote, the ITC terminated the antidumping remedy (pricing agreement) against Venezuela (Southern Tier Cement Committee, 2000c). The ruling on Mexico was a surprise to some analysts who had speculated that continued injury to the industry from Mexican cement imports would be difficult to prove following the withdrawal in late 1999 of Southdown, Inc., a major proponent of the original tariffs, from the industry coalition that was supporting the continuation of the antidumping remedies. Southdown had cited the strong U.S. cement market conditions in recent years and substantial control of imports by U.S.

Digitized by Google

producers as evidence that the tariffs were no longer needed. It was unclear whether CEMEX, the main Mexican company targeted by the antidumping order on Mexican cement, would appeal the ITC ruling based on a change of circumstances following its purchase of Southdown.

In terms of Government funding of construction projects, the cement industry had anticipated much higher spending levels in 1999 and 2000 on road and related infrastructure repair and construction as a result of the signing into law in June 1998 of the Transportation Equity Act for the 21st Century (TEA-21). This law authorized $216.3 billion in funding for the 6-year period from 1998 to 2003 for the purpose of upgrading the country's transportation infrastructure. The level of funding exceeded previous spending levels by an average of about 44% per State, and the bill contained substantial funding guarantees. Funding provided for various facets of highways, including new roads and bridges and existing infrastructure upgrades and repair, totals about $173 billion, of which about 95% was guaranteed. Estimates varied as to how much added cement consumption [typically 6 million to 8 million metric tons per year (Mt/yr)] would result from full-level TEA-21 spending, but nowhere near this level of added consumption had materialized as of yearend 2000. It appeared that the impact of delays in State funding (for cofunded projects) and of lag times between project initiation and actual cement consumption was greater than had been anticipated.

Environmental Issues.—Both mining and manufacturing are involved in cement production. As shown in table 6, approximately 140 Mt/yr of raw materials are directly or indirectly mined in the United States to produce cement, and the clinker that is imported converts to another almost 8 Mt/yr of raw materials, albeit mined outside the country. Calcareous feeds, such as limestone, make up about 85% of the raw materials mined by the cement companies themselves; most of the remaining materials are obtained locally as well. In addition, as shown in table 7, the cement industry burns significant quantities of fossil fuels. Most mines and quarries supplying the cement industry are open pit operations. Environmental issues affecting mining of cement raw materials are mostly local and are common to most surface mines; they include potential problems with dust, increased sediment loads to local streams, noise, and ground vibrations from blasting. Of greater concern, however, are the environmental impacts of the cement manufacturing process itself, most of which stem from the manufacture of clinker.

In 2000, U.S. clinker kilns burned about 15 Mt of fossil and/or other organic fuels (table 7). In the debate over climate change, the impact of greenhouse gases on atmospheric warming is a major issue. The most common greenhouse gas is carbon dioxide (CO_2), and fuel combustion and calcination of carbonate (limestone) feed in the clinker kilns both generate large quantities of this gas. Calcination basically follows the equation: $CaCO_3 \rightarrow CaO + CO_2\uparrow$. Although precise determinations of CO_2 emissions by the U.S. industry are unavailable from the companies themselves, reasonable estimates (within 5% to 10%) of the emissions for the industry overall can be made based on certain assumptions as to the composition of the raw materials and fuels consumed and the clinker produced. These assumptions are explained in more detail in the 1999 and earlier editions of this report, but generally, the production of 1 metric ton (t) of clinker releases 0.51 t of CO_2, and the combustion of fuels releases on the order of 0.4 to 0.5 t of CO_2, depending on the types of fuel consumed and the pyroprocessing technology used. Thus, approximately 1 t of CO_2 is released per ton of clinker, and very slightly less (because of the added gypsum) per ton of straight (unblended) portland cement. Based on the clinker production shown in table 5, the U.S. industry released about 77 Mt of CO_2 in 2000. Additionally, U.S. cement plants consumed electricity (table 8) equivalent to about 7 to 8 Mt of CO_2, but this "emission" generally would be assigned to the electrical power industry.

Although dwarfed by the collective CO_2 emissions of powerplants and motor vehicles, the cement industry is one of the largest remaining industrial sources of this gas and is perhaps the largest single industrial source (or possibly second to the iron and steel industry) of CO_2 not derived from the combustion of fuels. Because of this ranking, the cement industry receives more attention concerning its CO_2 emissions than it would like, notwithstanding the fact that its CO_2 emissions are only about 1.5% of the U.S. total (U.S. Environmental Protection Agency, 2001, p. ES-4). The concern of the cement industry with CO_2 continues to be the possibility that the Government, either under the obligations of international environmental treaties or by its own volition, will seek to substantially reduce the cement industry's emissions by such means as the imposition of carbon taxes, the enactment of emissions quotas, or the requirement that low(er) emissions production technologies be used.

As discussed in more detail in the 1999 edition of this report, the Kyoto Protocol, signed at the United Nations Framework Convention on Climate Change held in Kyoto, Japan, in 1997, calls for reductions in CO_2 output by countries to levels substantially below those in 1990, to be achieved by 2012. As of yearend 2000, the U.S. Congress had not ratified the protocol nor had most of the other signatories. To meet its Kyoto Protocol target (7% below 1990 emissions levels), the United States would need to reduce its emissions by 20% or more by 2012 from what they would potentially be at current emissions growth rates. Roughly similar reductions would apply to other countries bound by the protocol. Given that the overwhelming majority of nonagricultural emissions of CO_2 are from the burning of fossil fuels, any major reductions in CO_2 emissions would have to be through proportional reductions in energy consumption, and the economic ramifications of this could be substantial. Most objections to the Kyoto Protocol revolved around the fact that only the so-called developed countries would be bound by it (although all the others would be encouraged to reduce emissions), leaving them at economic disadvantage to countries not so bound. Various proposals for emissions trading, and receiving credit for so-called carbon-sinks, have been debated to reduce the potential economic impacts. In late November, the Sixth Conference of the Parties to the United Nations Framework Convention on Climate Change was held in the Hague (a followup meeting to that in Kyoto in 1997) to discuss these proposals, but no agreement was achieved.

There has been substantial interest in developing precise and auditable inventories of CO_2 and other greenhouse gas emissions to aid emissions reduction strategies. In mid-2000, the Intergovernmental Panel on Climate Change released its so-called good practices methodologies, designed to calculate national emissions levels (Intergovernmental Panel on Climate

Digitized by Google

Change, 2000).

For the U.S. cement industry, mandated major reductions in CO_2 emissions could require shutting a number of older plants, especially those operating wet kilns, and/or upgrading plant equipment to more efficient technologies. Upgrading, for various reasons, is already underway at many plants but is an expensive process. Mandated emissions reductions could force plants to burn less carbon-intensive fuel, for example, natural gas rather than coal. Many U.S. cement plants already are able to switch among a variety of fuels, but large-scale shifts of cement plants and other fuel-intensive facilities (e.g., powerplants) to natural gas could lead to local shortages and price increases for that fuel. An alternative emissions-reduction strategy, market permitting, would be to increase the output of blended cements and perhaps allow the addition of small amounts of inert extenders (as bulking agents) in straight portland cement. Either strategy would reduce the clinker (and hence emissions) component of the finished cement, which in turn would reduce total emissions by the cement industry or at least constrain emissions increases if cement demand (and output) grows. A major shift to blended cements could lead to local shortages of suitable pozzolans, as well as increased prices for them. The U.S. concrete industry is itself a significant direct consumer of pozzolans, which are used as a partial substitute for portland cement in ready-mixed concrete and some other concrete mixes. A recent review of CO_2 emissions reduction strategies, focusing on reductions of specific energy consumption, is given in Martin, Worrell, and Price (1999). Cement kilns are considered to be an environmentally benign way of burning a variety of hazardous and nonhazardous wastes, owing to the very high temperatures at which clinker is made and the long residence times of materials in the kiln. A waste fuel that has received recent attention in Europe is bone meal, which has become abundant through the necessity of slaughtering vast numbers of diseased livestock and which, from such contaminated sources, is unusable for most other applications (Whitehorn, 2001).

Another approach to reducing emissions from clinker manufacture is to use a noncarbonate source for some of the CaO in the kiln feed. A process patented by Texas Industries, Inc. (TXI), and known as CemStar, makes use of ferrous (particularly steel) slag as a CaO raw material in the kiln feed. As noted in a review by Perkins (2000), use of CemStar increases clinker output by as much as 10% or more, with commensurate reductions in unit CO_2 emissions. The process has been licensed to a number of plants and is reflected in the steel slag consumption data in table 6.

Other emissions of the cement industry include cement kiln dust (CKD), nitrogen and sulfur oxides (NOx and SOx, respectively), and dioxins and furans. The U.S. Environmental Protection Agency issued regulations concerning these and other emissions from the industry in 1999, but most of these regulations were still under one form or another of review or debate in 2000. Except for CKD (virtually all of which is captured and a majority of which is recycled to the kilns), the cement industry is not considered a major source of these pollutants compared with a number of other industries. The cement industry is nonetheless concerned about new emissions limits and prescribed monitoring methods, namely the degree that they can or cannot be realistically implemented and/or the emissions controlled. Many plants are already improving their burning systems to reduce NOx emissions; a review of methods to do this is given by Wahlquist (2000).

Production

In 2000, cement was produced in 37 States and in Puerto Rico. All of the facilities were in the private sector with the exception of one plant (Dacotah Cement Co.) that was State-owned. At yearend 2000, about 79% of U.S. portland cement output and 85% of its production capacity were foreign-owned, a major increase from the 68% foreign ownership status at yearend 1999 and mostly owing to the CEMEX purchase of Southdown. In addition to the portland and masonry cement plants, there were several grinding facilities that produced GGBFS from unground slag from domestic or foreign sources. When ground, this material (GGBFS) is sold to the cement and concrete industries as a cementitious additive; it is also known as "slag cement," but the use of this term is confusing as it already refers to a specific type of high GGBFS-content blended portland cement. GGBFS plants will not be dealt with in this report except to the extent that their product makes its way into blended cements, and with respect to the fact that all or most of them could grind clinker instead, should market conditions so warrant.

Although, technically, there were no new (greenfields) plant openings in 2000, a facility in Florida that had commenced clinker production in late December 1999 had its first output and sales of portland cement in January 2000 and reached full capacity production levels (clinker and cement) later during the year. One small grinding facility that had in recent years only been operated as a terminal resumed grinding on an intermittent basis. New plants are planned or are under construction in Colorado, Florida, Missouri, New York, and Texas.

Following the startup of clinker production at yearend 1999, Florida Rock Industries, Inc., had its first production and sales of portland cement from its new 0.68-Mt/yr Newberry, FL, plant in January 2000, a project reviewed by Cohrs (2001). The facility reached full output levels after several months of ramp-up operations. Suwannee American Cement Co. received some of its environmental permits to construct a greenfields plant near Branford, FL (Portland Cement Association, 2000b).

Many existing plants had expansion projects completed during the year or which were within 1 to 2 years of completion. A few of the larger projects will be mentioned here. Ash Grove Cement Co. was replacing the two wet kilns at its Chanute, KS, facility with a single dry kiln of about 1.5 Mt/yr capacity; the work was expected to be completed by mid-2001 (Ash Grove Cement Co., 2001). Blue Circle was adding a new kiln line at its Calera, AL, plant, with a completion date anticipated for 2002 (World Cement, 2000). The company also commissioned a new slag grinding mill at its Detroit, MI, clinker-grinding plant. Early in the year, Holnam, Inc., fired up its newly constructed second kiln line at its Midlothian, TX, plant. The new line doubled the plant's existing capacity to 2 Mt/yr (Arthur, 2000). Essroc Cement Corp. was planning to expand the capacity of its Speed, IN, plant by 75% by converting its long dry kiln to short dry technology. The work was anticipated to be completed around yearend 2001 (International Cement Review, 2000a). At yearend, Holnam broke ground for a new 2,000 Mt/yr dry kiln to replace the existing pair of wet kilns at its Holly Hill, SC, plant. The kiln was expected to come online

Digitized by Google

in mid-2003. Holnam was also constructing a new 1.9 Mt/yr dry kiln line to replace the three existing wet lines (total capacity 0.77 Mt/yr) at its Florence, CO, facility; the new line was targeted to start production in early to mid-2001. At yearend, Holnam announced its decision to proceed with a project to build a 4 Mt/yr greenfields cement plant in St. Genevieve County, MO. This would be the largest single kiln line in the country (Cement Americas, 2001). Lehigh Portland Cement Co. was replacing the four long dry kilns at its Union Bridge, MD, plant with a new, single, dry precalciner kiln. The new line was due to be fired in early 2001 (Barzoloski, 2000). At midyear, Lone Star completed the conversion of its Greencastle, IN, wet kiln to semidry technology, thereby almost doubling its capacity to 1.17 Mt/yr. This was the first semidry line in the country (Mining Engineering, 2001). In August, RC Cement Co. brought online a new finish mill at its Signal Mountain Cement Co. subsidiary in Tennessee; the project's new 0.72-Mt/yr kiln line was due to be fired up in early 2001, at which time the existing pair of wet kilns would be shut down (Maranzana, 2000). RC's subsidiary River Cement Co. was planning to expand the capacity of its Selma, MO, plant by about 0.4 Mt/yr (Portland Cement Association, 2000a). Late in the third quarter, Southdown, Inc. (prior to its takeover by CEMEX), completed the kiln line upgrade of the Kosmos Cement plant in Louisville, KY; announced in 1999; the plant is a joint ventured with Lone Star. Work on the new finish mill at TXI's Midlothian, TX, was completed late in the year and the company expected to have the plant's new kiln fired in January 2001. This will increase the plant's capacity to about 2.5 Mt/yr (International Cement Review, 2000b).

Portland Cement.—Portland cement was manufactured in the United States in 2000 at a total of 115 plants out of 116 claiming clinker grinding capacity (the remaining plant produced only GGBFS). There were also two portland cement plants in Puerto Rico. Seven of the portland-cement-producing facilities were only grinding plants (that did not produce their own clinker); one of these was operated only intermittently during the year, and several also ground slag in addition to clinker. The regional distribution of these plants, cement production and capacities, and yearend cement stockpiles are listed in table 3.

In 2000, production of portland cement rose by 2.4% to 83.5 Mt, a new record but still well below total consumption (table 9). Further, the production was slightly enhanced (0.27%) by the added production day (2000 was a leap year). The production shortfall continued to be met by imports (tables 18-22). As shown in table 3, portland cement production increases were noted in all but 10 districts. The decreases were all in districts accessible to imported cement. The top five producing States, in descending order, continued to be California, Texas, Pennsylvania, Michigan, and Missouri.

Cement (grinding) capacity increased by 6.0% to 103.4 Mt as a result of upgrades at several plants; large increases were reported in a dozen districts, and only four districts showed decreases. Capacity utilization was high virtually everywhere, although it fell slightly (to 80.7% utilization) for the country overall. Where the annual utilization rates appeared to be low or had fallen significantly, the cause was generally the coming on-stream of additional capacity, which was fully counted but not fully used during the year. Florida remained a case in point, with a new plant starting its grinding mill in January 2000 (clinker production commenced at yearend 1999) and upgrades coming on-line at other facilities. The capacity utilization figure is understated because it is calculated using only the production of portland cement, whereas the grinding capacities reported by the plants include that for masonry cement. If masonry cement production (table 4) is included, national grinding capacity utilization in 2000 recalculates to 84.9%, compared with 88.1% in 1999. Given the fact that reported capacities take into account shutdowns only for routine maintenance, the capacity utilization rates shown are likely close to full practical operational levels.

The 2000 district and national annual grinding capacities exceeded, sometimes by large amounts, the corresponding clinker production capacities listed in table 5. This is owing to a number of factors. Some districts have dedicated grinding facilities that import all of their clinker. It is generally easier and cheaper for an integrated plant to add grinding capacity than to add clinker capacity. Extra grinding capacity allows a plant to quickly increase product output and to change cement formulations by the expedient of importing clinker and/or cementitious additives. The exceptionally large excess grinding capacity in Michigan in part reflects restricted cement-shipping capabilities of one plant during the winter—all of its cement must be made (ground) and shipped during the open-water months.

The grinding capacity declines shown in a few districts may simply represent temporary mill shutdowns during upgrade projects or the permanent retirement of obsolete grinding equipment. In some years, declines may also reflect the transfer of some grinding capacity to nonclinker applications where the reporting company chose not to consider it as available for cement.

Yearend 2000 stockpiles of portland cement were 11% higher than at yearend 1999; although this change affects the apparent consumption statistics in table 1, it has little significance for the cement industry itself. Shifts in stockpiles can result from buildups or drawdowns related to maintenance and upgrade shutdowns of mills, changes in sales volumes, interruptions to delivery schedules, and the conversion of one type of cement to another higher tonnage type (such as portland converted to blended cement).

Although the sales of various types of portland cement are listed, split out, on table 16, data are not collected on the actual production of the different varieties of portland cement. However, it is likely that the production, for most types, is at least somewhat proportional to the sales in table 16, both in relative percentage and absolute tonnage terms, after adjustment for sales of imported cement (see tables 18-22). The import adjustment can only be approximate, because import tariff numbers only allow differentiation of clinker from hydraulic cement, and within hydraulic cement, differentiation only among gray portland (this would include most of the table 16 listings), white portland, aluminous cement, and "other" hydraulic cement. In terms of the gray portland imports, it may be assumed that the majority qualifies as Types I or II (imports into southern California include a lot of Type V). An import adjustment for white cement is made difficult because of problems with the import data (see the "Values" subsection under the "Consumption" section below). Finally, imports feed stockpiles, not just sales. The import cautions notwithstanding, it can at least be stated that production of Types I and II (or

Digitized by Google

hybrids thereof) accounted for about 90% of total portland cement output.

Portland cement producers in the United States ranged from those having a single, perhaps very small, plant to large, multiplant corporations having in excess of 10% of total U.S. capacity. The ranking of these companies in terms of production and capacity is complicated by how one defines the term "company;" some entities are subsidiaries of common parent corporations and some plants are jointly owned by two or more companies. If companies having common parents are lumped under the larger subsidiary's name, and if the joint ventures are apportioned, the top 10 companies at yearend 2000, in descending order of production, were Holnam, CEMEX (Southdown), Lafarge, Lehigh, Ash Grove, Blue Circle, Essroc, Lone Star, RC Cement, and TXI. Together, these accounted for 72% and 69% of total U.S. production and production capacity, respectively, and all except Ash Grove and TXI were foreign-owned as of yearend.

Masonry Cement.—Production of masonry cement (including plastic and portland lime cements) fell by 1% to 4.3 Mt in 2000 (table 4), following an almost 10% increase the previous year. Unlike portland cement, masonry cement production was virtually identical to its reported domestic consumption, and very little of that consumed was imported (table 9). The data in both tables 4 and 9, however, underrepresent true production and consumption levels of masonry cement, because it is common for masonry cement (particularly the portland lime variety) to be made at the job site itself, from purchased portland cement and lime. There are no data on this jobsite activity, but it is likely to be substantial. The reported production decline reflects lackluster demand during the year (see "Consumption" section below) and cold-weather-induced work delays towards yearend. In 2000, all but 5% of the masonry cement was reported by cement companies as having been made directly from clinker rather than starting from a finished portland cement. This ratio has not varied much in recent years.

Clinker.—Table 5 lists district-level information on clinker production, capacity, capacity utilization, and yearend stockpiles. Output of clinker increased by 2.8% to 78.1 Mt in 2000, yet another record. As with cement, clinker production in 2000 reflected a 0.3% increase owing to the 1-day longer leap year. The increase was widespread, with only a few districts (Illinois, Kentucky, Mississippi, and Tennessee; Arizona and New Mexico; and northern California) showing declines, and most of these were small. As in 1999, clinker was produced by a total of 111 integrated cement plants, operating 201 kilns. Two of these plants and kilns were in Puerto Rico. About 70% of the plants used dry-process kiln technology. Two facilities operated both wet and dry kilns, and one facility completed its kiln conversion during the year from wet to semidry technology (listed as dry in table 5).

California, Texas, Pennsylvania, Missouri, and Michigan, in descending order, remained the top five clinker-producing States in 2000. Combining companies as much as possible under common ownership, the top 5 companies had 49% of total U.S. clinker production and capacity, and the top 10 companies had about 72% of both. The top 10 companies, in descending order of production, were CEMEX (including Southdown), Holnam (remained first in capacity, however), Lafarge, Lone Star, Lehigh, Ash Grove, Essroc, Blue Circle, RC Cement, and TXI.

Apparent clinker capacity increased by 4.0% to 89.3 Mt/yr; as with production, the capacity statistic benefited from the additional workday in 2000. Capacity utilization fell slightly to 87.5% (from 88.5% in 1999), but there continued to be only very few districts that showed utilization rates below 85%. The low rate in Indiana was due to a kiln conversion (upgrade) shutdown for part of the year. With few exceptions, the capacity utilization rates depict an industry at full practicable production levels nationwide.

Annual clinker capacity and capacity utilization data are sensitive to reporting errors related to the classification of kiln downtimes. For each kiln, apparent annual capacity is calculated as the reported daily capacity times the "expected working year," which is the full year (366 days in 2000) minus the number of days that the kiln was shut down for routine maintenance. Emergency shutdowns, scheduled shutdowns for plant upgrades, and those for slow market conditions are not counted, except to the extent that they overlap the days planned for routine maintenance. Typically, one or two outages, totaling 1 to 4 weeks, are scheduled for annual routine maintenance, and this work mostly revolves around replacement or repair of the refractory brick linings in kiln and other pyroprocessing equipment. Company interpretations vary, however, as to what should be counted as routine maintenance, and those interpretational differences affect the length of the expected working year and hence the calculated annual capacity. This downtime uncertainty or sensitivity means that small changes in regional annual capacity or capacity utilization have little, if any, statistical significance. This differs from the grinding (cement) capacity data noted earlier, which are directly reported by the plants. The daily clinker capacities listed in table 5 should be viewed with caution as they are particularly sensitive to propagation of rounding errors.

Within the above constraints, average plant clinker capacity in 2000 was 0.82 Mt/yr, up by 3.7%, and average kiln capacity was 0.45 Mt/yr, up by 4.4%. Plants operating only dry (including one semidry plant) process kilns produced 75.5% of the total clinker (table 7), those operating wet kilns accounted for 22.5% of the clinker, and the two plants that operate both types of kilns contributed the remainder. The dry kiln contribution in 1999 was 73.7%.

Yearend 2000 clinker stockpiles totaled 5.3 Mt, up by 1.5 Mt, but the significance of this is uncertain. Clinker stocks are generally built up ahead of planned kiln shutdowns, most but not all of which are held in the winter months. Some clinker is also imported. Nevertheless, the yearend increase in 2000 is in line with reported monthly clinker production increases late in the year (and in all other months except May) combined with an 11% drop in portland cement sales in November and a 17% drop in December. The stockpile increase, combined with an increase in production, is consistent with the decline of 0.8 Mt in clinker imports for the year (table 22).

Raw Materials and Energy Consumed in Cement Manufacture.—Nonfuel raw materials used for cement manufacture may be divided into materials used to make the clinker and those added subsequently in the grinding phase (finish mill) to make the cement itself. The differentiation is primarily of environmental interest; materials used to make clinker are burned in the kiln and are associated with various chemical changes and emissions; those used in the finish mill

Digitized by Google

are merely comminuted. Table 6 lists these materials as well as the amount of imported (foreign) clinker ground. About 1.7 t of nonfuel raw materials are needed to make 1 t of clinker, and the ratio also approximately holds to make portland cement (provided that the foreign clinker used to make cement is also back-converted to raw materials). Limestone or other calcareous materials account for about 87% of the total raw materials required. The mass ratios among various major raw materials were essentially the same for 2000 and 1999. The listing of materials under headers like "Calcareous" and "Siliceous" is to some degree artificial because many of the raw materials supply more than one oxide.

The clinker versus cement differentiation of nonfuel raw materials is subject to reporting errors, as this was not requested prior to the 1998 survey and some plants remain unaccustomed to it. Accordingly, some of the increases in 2000 may simply reflect improved reporting rather than a net change in true consumption. Additionally, some materials may be inconsistently classified from year to year or among plants. For example, one plant's limestone might be another's cement rock; likewise with clay and shale and among the several ferrous slags. Furthermore, some materials are generally not routinely fully measured by the plant, most notably CKD, where the component automatically recycled to the kiln is generally unmeasured. Accordingly, the CKD consumption listed in table 6 (clinker column) is substantially too low. Increasing environmental interest in CKD may lead the industry to begin measuring this material more completely in the future.

Among the siliceous raw materials, some of the pozzolans appear to be out of balance with the sales (as a proxy for production) of blended cements listed in table 16. This is true especially for GGBFS, consumption of which is much too high for the sales of the appropriate blended cement. The explanation for this is that most of this slag was not consumed by the cement industry to make blended cements but was used as a grinding aid in States that allow an addition of a minor amount (up to about 3%) of GGBFS within Type I portland. However, the amount of GGBFS listed in table 6 is perhaps only 10% of the true consumption of this material by, ultimately, the concrete (especially ready-mixed) producers, who buy GGBFS directly from slag processors and blend it as a partial portland cement substitute into their concrete mixes. Likewise, the amount of fly ash listed in the table 6 cement column is but a small fraction of the roughly 9 Mt/yr of this material purchased directly by the concrete industry for use as a cement extender (American Coal Ash Association, 1999). It should be reiterated that table 6 reflects consumption by the cement producers, not the concrete manufacturers. The large increase in steel slag consumption (for clinker) in table 6 appears to reflect the increasing popularity of the CemStar process developed by TXI, as discussed earlier.

Table 7 lists the consumption of fuels by type of kiln process. Many cement plants are able to switch among a variety of primary fuel types, and many routinely burn a mix of fuels. It is difficult to analyze changes in the ratios among fuels on a national basis, save that the high costs of petroleum-based fuels and natural gas in 2000 led to widespread shifts back to coal and increased use of solid and liquid wastes. The decline in use of waste tires is surprising but may reflect unreported problems with environmental permits held or sought by specific plants. It could also represent data omissions or misinclusion of tires in the "Solid" waste rather than "Tires" category.

As in past years, dry plants produced the majority of the clinker and consumed the majority of fuels (although less fuel per ton of clinker), with the exception of wet process consumption of liquid waste fuels. High production costs associated with the wet kiln process made the cost savings achievable through use of liquid wastes (which the plants are paid to take) very attractive, and the very long residence times in the kilns made for environmentally efficient burning of this material.

Table 8 lists the consumption of electricity by the cement industry, differentiated by process type. As expected, dry process plants had a higher average unit electricity consumption that wet kilns, reflecting the complex array of fans and blowers associated with modern dry kilns. The average unit consumption for dry plants increased slightly in 2000, possibly reflecting the inclusion of one semidry plant that was converted from wet technology during the year. The large increase in unit consumption by plants operating both wet and dry kilns is of little significance, as it represents only two plants. The increase listed for grinding plants, which follows a decrease in 1999, may reflect increased output of GGBFS from some of these plants. Slag-processing plants have higher unit electricity consumption levels than do cement mills because slag is harder to grind and is ground finer than clinker.

Consumption

Apparent consumption of cement is listed in table 1 and rose by 1.5% in 2000 to 110.5 Mt. Although apparent consumption is a standard statistic for comparing consumption of various commodities, the measure of consumption preferred by the cement industry for its market analyses (because the data are available monthly and are sourced directly from the cement companies) is that of cement sales or shipments to final customers. These monthly data are listed totaled for 1999 and 2000 in tables 9 and 10. Consumption (sales) in 2000 of portland and masonry cement rose by 1.0% to 109.7 Mt. The definition of "final customer" is left to the reporting cement producer, but is generally understood to include concrete manufacturers, building supply dealers, construction contractors, and the like. The monthly data are collected in terms of the destination of sales (location of final customer, i.e., consumption by State), and by State or country of origin (manufacture). Although the monthly reports differentiate between portland cement and (portland-based) blended cement, both are included in the term "portland cement" in this report (including table 9).

Tables 11 through 16 list various annual survey data on or derived from shipments of cement reported by cement producers and import terminals. Some of the data, especially those in tables 12 and 13, look superficially similar to the data in tables 9 and 10, but there are important differences between the two data sets, particularly for portland cement. Tables 9 and 10 show the larger totals, and these data are believed to be more complete (especially regarding imported cement) and thus a better measure of true consumption levels. Tables 9 and 10 also show the true location of the sales (customers) for the cement; however, the cement could have been sourced elsewhere. In contrast, the regional data in tables 12 through 16 simply reflect the location of the reporting facilities, not their customers nor

Digitized by Google

necessarily where the cement was manufactured.

Examination of the data for Michigan and Ohio will illustrate the interpretational difference between the two data sets. Michigan consumed 3.5 Mt of portland cement in 2000 (table 9), but Michigan producers shipped almost 5.8 Mt (table 12) to final customers, not necessarily all in Michigan. Michigan was thus a net exporter of cement. Ohio consumed 3.9 Mt of portland cement, but its producers (and terminals) shipped only 1.2 Mt (table 12). Ohio was thus a net importer of cement. Nonproducing States like New Jersey import all of the cement they consume (table 9).

National Consumption.—In 2000, portland cement consumption grew by only 1.1% (compared with 5.0% in 1999) but still achieved a new record of 105.3 Mt (table 9). The imported cement component of this fell by 2.5% to 21.9 Mt; the decline was mainly because of domestic production increases, but imports still were about 21% of total consumption. However, the cement import volumes understate the importance of imports, because the country also brought in 3.8 Mt of clinker (table 22), equivalent to about 3.9 Mt of portland cement, so the true import dependence for portland cement in 2000 was closer to 25%. Masonry cement consumption declined by 0.5% to 4.3 Mt from the record level of 1999. The import component of this was only about 1%.

Because cement is a key construction material, growth in cement consumption reflects trends in construction spending. Overall construction spending levels increased by 2.1% in 2000 (relative to revised 1999 data) to $706.9 billion (constant 1996 dollars), according to U.S. Census Bureau data quoted by the Portland Cement Association (2001). Within this total, residential construction grew by 2.1% to $323.7 billion, of which single-family dwellings accounted for $204.8 billion, up by 1.1%. Despite continued very low mortgage rates, the residential construction growth rate in 2000 was modest compared with the 6% level seen in 1999 and reflected a generally slowing economy; much of the growth was in residential improvements rather than new units. Private nonresidential construction grew by 3.6% to $179.7 billion, powered by a 12.0% increase in office construction to $47.6 billion. This performance likely reflects the long lead times on orders placed in 1999 or earlier. Industrial construction fell by 6.2% to $27.4 billion and followed a 17.2% drop in 1999. Public sector construction spending was essentially stagnant (down by 0.2%) in 2000 at $151.8 billion. Public building construction increased by 2.8% to $70.4 billion. The important road construction component of public spending fell by 3.6% to $45.2 billion, a disappointment given the anticipated increase in spending related to TEA-21 funding, and the 8.8% (revised) spending increase in 1999. The explanation, in part, was that a higher than anticipated percentage of TEA-21 work during 2000 was for repairs rather than for more concrete-intensive new construction. Further, the slowing general economy was apparently hurting State revenues and hence State contributions to projects that involved joint State and Federal funding sources.

In contrast with recent years, the growth rate in overall construction spending in 2000 was higher than that, in tonnage terms, of portland plus masonry cement consumption. In the latter half of the 1990s, an increase in "penetration rate" (tons of cement consumed per million dollars of construction spending) was seen more or less each successive year. The improved penetration rate was generally credited to promotional efforts by the cement industry, in some years aided by moderate (relative to other construction materials) cement price increases. For example, in 1996, $1 million in construction spending "bought" 147.9 t of cement, and in 1999, $1 million (in 1996 dollars) "bought" 156.7 t of cement. Despite the virtually stagnant cement prices in 2000 (see "Values" subsection that follows), the penetration rate per $1 million (1996 dollars) declined to 155.2 t. The reasons for the decline are unclear, but probably include a combination of factors. Ignoring speculation on construction spending data accuracy (caused by to reporting delays, for example) and the likelihood of revisions to the 2000 inflation rates, major factors could be lag times in construction schedules relative to payment reporting, construction design (i.e., use of concrete versus competing construction materials), construction categories (e.g., single family versus multiple family dwellings versus roads versus factories, etc.), and type of work (e.g., concrete-intensive new construction versus less concrete-intensive repairs). Regarding the type of work, it might be speculated that, in a slowing economy, new construction might be deferred in favor of repairs to existing structures. Another factor, although difficult to quantify, is the fact that even the USGS monthly cement surveys do not capture 100% of the cement imports, but these missing imports are being consumed nonetheless. If this missing material amounted to just 1 Mt more in 2000 than in 1999, the penetration rate for 2000 would be unchanged from that in 1999. Yet another factor, also difficult to quantify, is that the true total consumption of hydraulic cement in the United States would include that of cementitious or pozzolan extenders bought directly by the concrete producers. These extenders have been mentioned in the raw materials discussion in the "Production" section and also will be discussed in the "Types of Portland Cement Consumed" subsection that follows; the tonnages involved (especially pre-1998) are not known with certainty, but would likely be in the range of 7 Mt/yr to 12 Mt/yr for the period 1996-2000. Finally, total construction spending involves many material and other costs (e.g., labor) besides those for cement or concrete.

Table 9 lists consumption of portland cement by State, and the general origins of the (total) cement consumed. About half of the States showed consumption declines, although many of these were small and likely would have registered a net increase for the year but for cold-weather-induced declines almost nationwide in November and December. Consumption increases were maintained in most of the strong-performing States of recent previous years, although strong increases (of 0.1 Mt or more) were seen only in California, Colorado, Florida, Nevada, and Virginia. Texas, usually a strong performer, managed to eke out a modest increase courtesy of the northern half of the State. Overall, in contrast with recent years, consumption in the southeastern Atlantic and Gulf Coast States was generally weak throughout the year, notably southern Texas (except during the summer). Several of the Rocky Mountain States, notably Utah, showed a slowdown in consumption, although Nevada remained very strong. Consumption grouped by census district is listed in table 10. In terms of portland cement, the 10 largest consuming States, in declining order, were California, Texas, Florida, Ohio, Illinois, Michigan, Georgia, Pennsylvania, Arizona, and New York. These combined had 53.5% of the U.S. total consumption.

Digitized by Google

Consumption of masonry cement also declined in about half of the States, but most of the declines were small. As noted in the "Production" section, data for masonry cement sales to final customers (table 9) underrepresent true consumption because it is common for masonry cement to be mixed from components at the job site rather than being brought in as a finished product. Also, the data exclude the output of a small number of small masonry cement blending plants, which are treated instead as final customers for portland cement. The very small (reported) consumption decline is likely because of to late year cold weather construction delays compared with the warmer 1999 winter.

Table 11 lists portland cement shipments to final customers in terms of transportation method. As in previous years, bulk deliveries by truck directly from plants or via terminals continued to dominate deliveries to customers. In contrast, railroad and waterborne transport were the most important methods of shipping cement from plants to terminals.

Values.—Tables 12 through 14 list mill net values provided by the plants and import terminals for their total shipments to domestic final customers of gray portland cement, white cement, and masonry cement. Because value data are highly proprietary and some companies express misgivings about providing value data of any type, values are not requested for shipments by individual types of portland cement. However, the tonnages shipped, by type, are reported (table 16). For the value of total shipments, no distinction is made between bulk and container (bag) shipments; however, container shipments would be expected to have higher unit values. Regional values for white cement have been lumped with those for gray portland cement, with the exception of the national total for white in table 14. Fewer than 10% of respondents to the 2000 survey declined to provide mill net value data—a modest improvement from the 1999 survey. Where value data were not provided, values supplied by plants in the same market area were averaged and applied as an estimate.

Mill net values for integrated plants can be defined as the (sales) value at, or free on board (f.o.b.), the manufacturing plant, including any packaging charges but excluding any discounts and shipping charges to the final customers. For independent terminals, particularly import terminals, the equivalent statistic sought would be the terminal net value. In the case of imports, this would essentially represent the cost, insurance, and freight (c.i.f.) value of the imports plus unloading and storage costs plus the terminal's markup.

Because the values listed in table 12 incorporate more than one type of portland cement, in both bulk and bag shipments, and some overall estimates, readers are cautioned that the values listed should be considered to be estimates, even though they are presented unrounded. Indeed, the mill net values are better viewed as price indices for cement, suitable for crude comparisons among regions and during time. Most especially, the unit value data cannot be viewed as actual shopping prices for cement. The data for portland cement are assumed to be dominated by bulk sales of the Types I and II varieties.

The average mill net value of portland cement in 2000 was $77.34 per ton, up by only 0.2%— a change of no statistical significance. Combined with a 2.4% increase in shipment tonnage (table 12), the total value of shipments rose by 2.6% to $7.8 billion. The same average unit value applied to the larger portland sales tonnage in table 9 yields a total value of $8.1 billion, up by 1.4%. The lower percentage increase in the value of the table 9 sales reflects the inclusion therein of a higher tonnage of (inexpensive) imported material than in table 12. Although the tonnage of imported cement grew by 0.7% in 2000, the unit value of the imports fell by 2.2% to $49.57 per ton (tables 18-22). Another constraint on portland cement prices continued to be that ready-mixed concrete companies (customers), for cost and performance reasons, were using a substantial fraction of cementitious or pozzolanic extenders in their mixes, which they would blend themselves, and were thus buying less straight or blended portland cement than they would have otherwise. By comparison with the average customs value (comparable to mill net plus, possibly, shipping to the export terminal) of imported gray portland cement, which was $35.50 per ton (table 20), and which is a rough indicator of sales prices in foreign countries, U.S. sales prices were very high by world standards. This made the United States a very attractive export target for many foreign producers.

Table 13 lists masonry cement sales and values in terms of the location of the reporting facilities. The average unit value of sales rose by 4.1% to $107.42 per ton and total sales rose by 2.6% to $459 million ($465 million for the volume in table 9). It should be noted, however, that the mill net values for masonry cement contain more component estimates than those for portland cement, and for a number of respondents, the masonry cement mill net values appear to have been reported on a bulk-equivalent basis instead of being inclusive of bagging charges.

Table 14 is a summary of cement unit values for the country overall. The data for white cement should be viewed with caution because there are only a few producers and importers of this product, and a significant share of white cement sales to final customers is as (marked up) resales by gray cement companies. Additionally, white cement includes a larger component of relatively costly package shipments, of imported material, and of estimates overall. Thus, the 4% unit mill net value decrease in 2000 to $159.45 per ton, if real, may not be statistically significant. A discussion of prices for imported white cement is given in the "Foreign Trade" section that follows.

The only data for domestic delivered prices for cement are those for Type I portland (per short ton) and masonry cement (per 70-pound bag) published monthly by the journal Engineering News-Record. The data represent a survey of customers, which most likely are ready-mixed concrete producers for portland cement and building supply depots for masonry cement, in 20 U.S. cities. The 20-city average delivered price in 2000 for Type 1 portland cement converts to $88.79 per metric ton, up by 1.7%, and ranged by only $1.29 per ton during the year. In contrast to some recent years, prices declined in the fourth quarter from their summer highs, reflecting cold-weather-related construction activity declines in the winter. The $12.18 difference between the Engineering News-Record average price and the average mill net value for gray portland cement in table 14 is an indicator of the approximate average delivery charge for bulk cement. This was significantly higher than the $10.86 per ton delivery differential in 1999 and likely reflects, at least in part, the higher fuel costs in 2000. District variations in mill net values in table 12 do not parallel very well the variations among Engineering News-Record prices for comparably located cities, possibly reflecting

Digitized by Google

local transportation and related variables and the fact that the mill net regionality (table 12) reflects the location of the survey respondent, not the customer. The Engineering News-Record 20-city average for masonry cement in 2000 was $6.23 per bag, which literally converts to $196.21 per ton and which was a 26% increase from the price in 1999. The average price and the price shift both greatly exceed the $107.42 per ton (up by 4%) mill net value shown in tables 13 and 14. The large differences for masonry cement would seem excessive, even accounting for a large component of packaging, handling, and (higher) delivery charges, and may reflect price reporting inaccuracies in either or both surveys.

Cement Customer Types.—Data on (portland) cement usage is collected on the basis of the types of customers to whom the cement is sold (table 15) rather than the direct application itself. The distinction is that a given customer, although classified in one category, may in fact have used the cement in more than one way. The data in table 15, as with values, are approximations. The main reason for this is that the surveys request more details (user categories) than many respondents are able to provide. Although much improved in recent years' surveys, there remain a number of companies or plants that either do not track their customers by user type at all or do so only broadly. A persistent problem is that of overlap of categories, the most common example of which is in cases where the customer is a ready-mixed concrete producer that is also engaged in road paving. The dilemma for the respondent is whether to assign the sales to the "Ready-mixed concrete" or to the "Contractors—road paving" subcategory on the form or whether to attempt a split. Further, for several user categories, the subset "Other" commonly gets used as a catch-all instead and is thus overused. Where estimates are made, either by the companies themselves or by the USGS, there is a bias towards the major usage categories; the minor categories are, therefore, likely underrepresented. As with the shipment data in table 12, the regional divisions in table 15 are the locations of the respondents, not the customers.

Notwithstanding these limitations, a number of comments on cement user types in 2000 can be made. As in past years, the dominance of ready-mixed concrete producers in the cement market is very evident. Ready-mixed concrete companies purchased almost 75 Mt of portland cement in 2000, or almost 74% of total sales, although there is undoubtedly significant overlap with the almost 5 Mt assigned to road paving contractors (table 15, footnote 5) and with the 1 Mt assigned to the "Government and miscellaneous" category. Compared with the respective levels in 1999, the ready-mixed tonnage in 2000 was up by 3.4%, the road paving category was down by 18%, and the two combined increased by 1.8%. Because the ready-mixed plus road paving combination would be expected to closely track the 2.4% increase in total (all categories) portland cement sales, some of the ready-mixed tonnage would be better assigned to the road paving category. That the road paving tonnage is likely too low is further supported by the 3.6% decline in road and highway construction spending noted earlier. A transfer of just 0.9 Mt, either all from the ready-mixed category or split 50-50 with the "other or unspecified" contractor subcategory, to the road paving category would shrink the road paving tonnage decline for the year to 3.6%. But this would not be statistically justified given that the overall error range in the table 15 data likely exceeds this adjustment amount significantly. Further, the tonnages do not reflect some of the imported cement used by ready-mixed concrete companies and road pavers.

Portland cement sales to concrete product manufacturers increased by 10.4% to 13.5 Mt, with sales to brick and block manufacturers up by 9.1% to 6.1 Mt; precast concrete companies, up by 22% to 3.1 Mt; and pipe manufacturers up by 8.2% to 1.7 Mt (table 15, footnote 4). These growth rates exceed those for building construction noted earlier, but this may not be suspicious given the large component of value added in building construction. Overall consumption by contractors fell by almost 13% to about 7.1 Mt, with large percentage declines seen in all the specific categories, not just road paving (table 15, footnote 5). These declines, again, seem to be out of step with the construction spending levels noted earlier but in part may reflect consumption of imported cement not captured by the annual survey. Sales to building materials dealers fell by 16.3% to 3.5 Mt, which would appear to be out of phase with the increased spending levels for residential construction; the decline probably, at least partially, reflects incomplete reporting.

The general category "Oil well, mining, waste" lumps minor categories that are prone to underrepresentation. Portland cement sales to customers engaged in oil well drilling were up by 41% to 1.2 Mt (table 15, footnote 6), although the rate of change is out of line with the almost 80% increase, to 1.0 Mt, in sales of oil well cement (table 16). The discrepancy is hard to evaluate because the user tonnage is likely underreported, and ordinary types of portland cement (e.g., Types I, II), which tend to get assigned to major use categories, can be used for shallow oil wells in lieu of specialized oil well cements. A large increase in such sales was expected, however, given higher crude petroleum prices and drilling levels during the year. There was an almost 48% increase in the average weekly Baker Hughes (oil and gas drilling) rig count for 2000 (Oil & Gas Journal, 2001). Reported sales to mining companies fell by 28%, but the data are likely incomplete and subject to large relative errors because of the small tonnages involved. A large decrease in 2000, however, was expected given generally depressed metal commodity prices during the year and anecdotal accounts of mine closures and layoffs. Cement is used by mining companies as an agglomeration agent for heap leaches and in concrete for machinery foundations and for backfill of underground excavations.

Types of Portland Cement Consumed.—Sales to final customers of varieties falling within the broad definition of portland cement are listed in table 16. In 2000, Types I and II, combined, accounted for 88% of total portland sales, a typical proportion though slightly lower than in 1999. As noted in the introduction, the annual survey tonnages (e.g., table 16) are smaller by several million tons than those derived from the monthly surveys. It is believed that most of the "missing" tons are imports, and it is known that the great majority of cement imports are of Type I and II portland. Accordingly, the entries for Types I and II and the grand totals in table 16 could be augmented by about 5 Mt and 4 Mt in 1999 and 2000, respectively. Minor augmentations would also be justified for the white cement and Type V categories. Reported sales of Type V portland cement jumped by 46% in 2000, but much of this increase can be accounted for by a reclassification of some Type I and II material made and sold in California based on its

Digitized by Google

actual chemical performance (Type V cements exhibit high sulfate resistance).

Blended cement sales in 2000 grew by 8.6% to 1.3 Mt, representing 1.3% of total portland cement sales, about the same as in 1999. The 2000 sales (table 16) of blended cements are slightly higher than those derived from the monthly surveys (1.2 Mt and 1.2% of total portland plus blended sales), but the difference appears to be of little statistical significance. Overall, the proportion of total blended to total portland cement sales have remained virtually unchanged during the past several years, despite anecdotal evidence that concrete producers (particularly of ready-mixed product) have increased their use of cementitious extenders during this period. Evidently, although blended cement paste is becoming more popular with the concrete producers and their customers for cost and performance reasons, the concrete companies find it cheaper to do their own purchasing of extenders and their own blending rather than purchasing blended cements from the cement companies.

Notwithstanding similar total blended cement sales tonnages during the years, the ratios among specific types of blended cement have been variable. In 2000, sales of blends containing natural pozzolans fell by almost 16% (relative to levels in 1999) to 0.2 Mt; those of blends containing GGBFS rose almost by 29% to about 0.4 Mt; sales of blends with fly ash rose by 27% to 0.4 Mt; and sales of miscellaneous blended cements (e.g. containing CKD or silica fume) dropped by 9% to 0.3 Mt. In contrast, sales in 1999 (relative to 1998) of natural pozzolan blended cements declined by 19%; blends with GGBFS were up by 81%; those with fly ash were down by 27%; and those with miscellaneous pozzolans rose by 47%. For the 2000 blended cement sales, the tonnages listed are in line with the raw materials consumption (for cement rather than clinker) shown in table 6, except for blends with GGBFS and "Other pozzolans." The comparisons assume a typical pozzolan content in blended cement of 15% to 30% and that none of the pozzolan consumption in table 6 was for masonry cements. For GGBFS, the consumption for cement listed in table 6 is two to three times the amount needed to make the blended cement sold (table 16). The excess represents material used in the finish mills as a grinding aid; this is permitted within Type-I portland designations in some States provided that the slag content in the cement does not exceed about 3%. Although actual consumption data were lacking, based on the reported capacities of various slag-grinding facilities, it may be estimated that the amount of GGBFS consumed to make cement (table 6) is likely only about 10% of that which ultimately makes its way into concrete. Likewise, the amount of ash consumed for cement is only a small fraction of the 9 Mt reported as consumed for cement (other than for clinker) and concrete manufacture in 1999 (American Coal Ash Association, 1999) and probably in 2000 (actual 2000 data are unavailable); the inference is that most of this consumption is directly by the concrete manufacturers.

White portland cement sales increased by about 5%, but some of the cement may represent material that was actually sold within a white or colored masonry product. Oil well cement sales rose by almost 80%, reflecting substantially increased drilling activities during the year.

Foreign Trade

Tables 17 through 22 list trade data from the U.S. Census Bureau. Exports of hydraulic cement and clinker (table 17) increased in 2000 but, excepting sales to Canada, were essentially insignificant, and overall, the exports continued to be of almost no consequence to the U.S. cement economy. Almost all of the exported material was cement.

The U.S. cement economy continued to be significantly import dependent, although total imports of hydraulic cement and clinker (tables 18-19) declined by 2.3% to 28.7 Mt (including Puerto Rico). This was the first annual decline since 1992 and reflected a combination of a slowing growth in demand and an increase in domestic production capacity. The import tonnage decrease was in stark contrast to increases of 22% in 1999, 37% in 1998, and 24% in 1997. The 2000 tonnage represents approximately 25% of the total world trade in cement and clinker, based on global estimates (International Cement Review, 2001). The average unit c.i.f. value of imports fell by 1.4% to $48.72 per ton; the decline was a combination of a 4.0% decrease in base (customs) value to $37.44 per ton and an 8.4% increase in combined shipping (mostly fuel-related) and insurance costs to $11.28 per ton.

The hydraulic cement component of imports (derived by subtracting clinker imports in table 22 from the table 18 data) totaled 24.9 Mt, virtually unchanged from that in 1999. Gray portland cement imports were 95.7% of this total and were up by only 0.7% (table 20). The c.i.f. value of gray portland cement imports fell by 2.3% to $46.65 per ton, within which the customs value fell 5.1% to $35.50 per ton, and the freight and insurance charges rose by 7.7% to $11.15 per ton. In 1999, the customs value had fallen by 4.7% and the shipping charges had risen by almost 10%. The total c.i.f. value of gray portland imports fell by 1.7% to $1.11 billion. Customs values in 2000 ranged from $21.13 per ton for cement from the Philippines to $51.81 per ton for Canadian cement. Shipping charges ranged from $3.43 per ton from Canada (railroad) to $24.07 per ton from the Philippines, but there was considerable overlap of shipping charge rates among various source countries and regions and the cement landing points (table 19); because of this overlap and the large number of variables within shipping charges, no firm shipping charge trends could be discerned. As noted in the "Values" subsection, the customs values listed are much lower than the U.S. mill net and/or terminal net values of portland cement sold to final customers (tables 12 and 14), making the United States an attractive market for surplus foreign production, and making it relatively easy for U.S. importers to absorb rising transportation costs, even for material sourced from vast distances.

Although Thailand replaced Canada as the largest single source of hydraulic cement and clinker imports combined, in 2000, Canada remained the largest source of gray portland cement (table 20). Gray portland imports from Canada fell by 3.5% in 2000 to 3.9 Mt. Thailand was second, with 3.6 Mt, up by 16.3%. China, which had been second in 1999, was third with 3.3 Mt, down by 19.3%.

White cement imports are listed in table 21, and rose by almost 12% during the year to 0.92 Mt. The unit value (c.i.f.) rose by 1.2% to $110.70 per ton. However, this average value and several of the specific country annual average values appear to be too low (see, for example, the entries for Norway and

Digitized by Google

various Asian countries), reflecting very low unit values on certain individual monthly shipments (not shown). Likewise, the import tonnage appears to be too high. Unless reflecting dumped material, the most likely explanation for the low unit values is that the data include some gray portland cement, supposed to be reported under the Harmonized Tariff Schedule of the United States (HTS) code 2523.29.00 or that the importers mistakenly invoiced under the white cement HTS code (2523.21.00). Coding errors are difficult to verify, but past experience indicates that they do occur, though infrequently. Apart from the low overall value, evidence for misinclusion of gray cement is also found in some price differences between imported gray and white portland cement. For example, the 2000 imports of white cement from Indonesia calculate to a (suspiciously low) unit value (c.i.f.) of $54.61 per ton, which was only $10.43 per ton more than the unit value for imported Indonesian gray portland cement. This white cement premium is far smaller than normal, even considering expected general variability because of the imports perhaps comprising a mix of bulk and bag shipments. For U.S. cement imports overall, the premium for white cement was $64.05 per ton, and that for overall sales (table 14), $82.84 per ton. Finally, the white cement import tonnage appears to be out of line with the market for this material. Although the white cement market is very difficult to analyze—it being a fairly specialized product that is sensitive to a relatively small number of individual construction projects—the import tonnage increase exceeds the construction spending trends noted earlier. A final indication of problems with the white cement import data is that the total import volume exceeds the total white portland cement sales volume in table 16, which is inclusive of sales of domestically produced material. The excess appears to be much larger than could be reasonably accommodated by apportioning some imports to masonry cement sales (not included in table 16) or to yearend stockpiles. However, despite misgivings about some of the entries in table 21, the data therein for at least the major country sources calculate to realistic unit values and thus appear to be accurate. In 2000, Mexico was the largest source of white cement imports, followed by Canada, Denmark, and Spain.

Imports of clinker are listed in table 22. Total imports in 2000 fell by 17.7% to 3.8 Mt, and the unit c.i.f. value of the imports rose by 1.8% to $43.13 per ton. However, the data for both years are bolstered by the inclusion of a small quantity of very expensive aluminous cement clinker from France, the cement from which has very different applications than those for portland cement. If the French material is removed, the total remaining imports drop to 3.7 Mt (down by 17.1%), at a unit customs value of $29.41 per ton (down by 3.7%), and a unit c.i.f. value of $40.13 per ton (up by 2.2%).

Thailand continued to be the largest country source of the clinker imports, followed by Canada, which had been the largest source in 1999. The remaining major suppliers of clinker to the United States, in decreasing order, were Turkey, Colombia, China, and the Republic of Korea; neither Korea nor Turkey had supplied clinker to the United States in 1999. Excluding aluminous cement clinker, customs values for imported clinker ranged from $18.70 per ton for Chinese material to $51.42 per ton for imports from Canada. Thailand clinker had an average customs value of $19.82 per ton. Because of shipping costs, the price range was less extreme on a c.i.f. basis: Chinese clinker was $27.22 per ton, Canadian clinker was $53.67 per ton, and Thailand clinker was $35.10 per ton.

Imports of cement and clinker, by customs district of entry, are listed in table 19. New Orleans continued to be by far the busiest entry point for both cement and clinker; Detroit had been the largest clinker import venue in 1999. Much of the material coming into New Orleans was destined to be transferred onto barges for transport up the Mississippi River system. In terms of serving local markets, the largest cement-importing States were California, Florida, and Texas.

World Review

Individual country cement production data are listed in table 23. The data for some countries may include their exports of clinker. Although the data are supposed to include all forms of hydraulic cement, the data for the United States are for portland plus masonry cement only, and the data for some other countries also may not be all inclusive. Because data for many countries are estimated, the annual world totals (which have been rounded) must be viewed as estimates. As estimated, world hydraulic cement production increased by about 2.5% in 2000 to 1.64 Gt.

With production reported at 583.2 Mt, China was by far the largest cement producer in the world in 2000. Although precise data are lacking, India was in second place, and the United States was in third. The remainder of the top 15 cement-producing countries in 2000, in decreasing order, were Japan, the Republic of Korea, Brazil, Germany, Italy, Turkey, Russia, Thailand, Mexico, Spain, Indonesia, and Egypt. These top 15 countries accounted for about 75% of total world production and much of the growth in world production in the past decade. China alone, since 1995, has increased its output by 107 Mt/yr.

On a regional basis, Asia again accounted for about 59% of the world total production. This region, particularly Southeast Asia, was slowly recovering from the economic crisis that began in late 1997, and local cement production and consumption levels among the major cement economies increased in 2000; consumption, however, had yet to recover to precrisis levels. This meant that there were still substantial regional cement surpluses available for export at low base prices. Because of higher fuel (hence transportation) costs and generally weaker economies in the export target countries (particularly the United States), the cost advantage of importing cement from Southeast Asia was somewhat less than in 1999.

Europe retained its position as the second largest producing region; Western Europe accounted for 11.6% of world production, and Eastern Europe, 2.6%. North America, including Mexico, was the third largest producing region, with 8.1% of the total, and Latin America and the Caribbean had 5.4% of world output (this would be 7.3% if Mexico were included here). The Middle East, including Turkey, produced 6.3% of the world's cement, and Africa contributed 4.4%. Countries of the former Soviet Union produced only 2.9% of the world's cement in 2000 but had a great deal of surplus production capacity available.

There continued to be a large number of cement plant construction and/or modernization projects throughout the world, in many regions spurred by privatization programs and by the need for plants to conform to increasingly universal and stricter environmental standards. Much of the international investment was by a few major international cement companies,

Digitized by Google

most based in Europe. For the most part, these were the same companies that controlled the U.S. cement industry. Geographic diversification of holdings was seen as an advantage, as it allowed a spreading of investment risk among many countries, a market share in regions of large economic growth potential, and access to a diversity of supply sources as needed. Many of the new plants under construction were very large, and many were geared, at least partly, to exports.

Outlook

Cement industry analysts at yearend were anticipating fairly stagnant or declining market conditions in 2001, followed by a small decline in demand for the next year or two, followed by a resumption in steady demand growth, albeit at modest rates of 1% to 3% per year, for the next few years thereafter. The pessimistic short-term outlook was based in part on the cold-weather-induced drastic falloff in cement consumption in November and December 1999 and a general slowdown in the U.S. economy, which looked not to be short-lived. Having been disappointed in 1999 and 2000 by highway construction levels that fell well short of predictions under the TEA-21 funding scenarios, the industry was adopting a wait-and-see attitude towards highway spending levels in 2001 though remaining optimistic that the TEA-21 funding would eventually generate large cement sales.

New plant and/or capacity expansion projects planned or underway in the United States total about 25 Mt/yr of new capacity coming on-line by 2005. Whether or not all of these projects come to fruition, significant capacity additions are certain. These additions likely will substantially reduce the need for imported cement and clinker, although plenty of this material was expected to remain available at attractive base prices. With the termination of antidumping remedies against Venezuela, it was expected that imports from that country could increase at the expense of material from other regional exporters.

Although there was little expectation that the Kyoto Protocol would be ratified, the industry expected that pressures to reduce emissions of CO_2 and that other pollutants would increase, and several companies were taking steps to adopt proactive policies on their plants' environmental performances.

e/ Estimated. r/ Revised.

1/ Portland and masonry cements only, unless otherwise indicated.

2/ Excludes Puerto Rico.

3/ Includes cement produced from imported clinker.

4/ Shipments are to final customers. Includes imported cement. Data are based on annual survey of individual plants and terminals and may differ from tables 9 and 10, which are based on consolidated monthly shipments data from companies.

5/ Value at mill or import terminal of portland (all types) and masonry cement shipments to final domestic customers. Although presented unrounded, the data contain estimates for survey nonrespondents.

6/ Total value at mill or import terminal of cement shipments to final customers divided by total tonnage of same. Although presented unrounded, the data contain estimates for survey nonrespondents.

7/ Hydraulic cement (all types) plus clinker.

8/ Hydraulic cement, all types.

9/ Production (including that from imported clinker) of portland and masonry cement plus imports of hydraulic cement minus exports of cement minus change in stocks.

10/ Total hydraulic cement. May incorporate clinker exports for some countries.

TABLE 2
COUNTY BASIS OF SUBDIVISION OF STATES IN CEMENT TABLES

State subdivision	Defining counties
California, northern	Alpine, Fresno, Kings, Madera, Mariposa, Monterey, Tulare, Tuolumne, and all counties farther north.
California, southern	Inyo, Kern, Mono, San Luis Obispo, and all counties farther south.
Chicago, metropolitan	Cook, DuPage, Kane, Kendall, Lake, McHenry, and Will Counties in Illinois.
Illinois	All counties other than those in metropolitan Chicago.
New York, eastern	Delaware, Franklin, Hamilton, Herkimer, Otsego, and all counties farther east and south, excepting those within Metropolitan New York.
New York, western	Broome, Chenango, Lewis, Madison, Oneida, St. Lawrence, and all counties farther west.
New York, metropolitan	New York City (Bronx, Kings, New York, Queens, and Richmond), Nassau, Rockland, Suffolk, and Westchester.
Pennsylvania, eastern	Adams, Cumberland, Juniata, Lycoming, Mifflin, Perry, Tioga, Union, and all counties farther east.
Pennsylvania, western	Centre, Clinton, Franklin, Huntingdon, Potter, and all counties farther west.
Texas, northern	Angelina, Bell, Concho, Crane, Culberson, El Paso, Falls, Houston, Hudspeth, Irion, Lampasas, Leon, Limestone, McCulloch, Reeves, Reagan, Sabine, San Augustine, San Saba, Tom Green, Trinity, Upton, Ward, and all counties farther north.
Texas, southern	Brazos, Burnet, Crockett, Jasper, Jeff Davis, Llano, Madison, Mason, Menard, Milam, Newton, Pecos, Polk, Robertson, San Jacinto, Schleicher, Tyler, Walker, Williamson, and all counties farther south.

1/ Reported annual grinding capacity based on fineness necessary to grind individual plants' normal product mixes, making allowance for downtime required for routine maintenance.
2/ Includes one plant that reported portland cement (clinker) grinding capacity but no production of portland cement.
3/ Includes cement produced from imported clinker.
4/ Includes imported cement. Includes mills and terminals.
5/ Includes data for white cement.
6/ Data may not add to totals shown because of independent rounding.
7/ Total stocks include inventory, not included on a district basis, held by independent importers.

TABLE 5--Continued
CLINKER CAPACITY AND PRODUCTION IN THE UNITED STATES IN 2000, BY DISTRICT

(Thousand metric tons unless otherwise specified)

District	Active plants 1/ Process used Wet	Dry	Both	Total	Number of kilns	Daily capacity	Average days of routine maintenance	Apparent annual capacity 2/	Production	Percentage of capacity utilized	Yearend stocks 3/
California, northern	--	3	--	3	3	8.7	33.0	2,872	2,721	94.7	145
California, southern	--	8	--	8	17	26.2	26.1	8,979	7,897	88.0	560
Oregon and Washington	1	2	--	3	3	6.3	35.3	2,085	1,721	82.5	88
Total or average 5/	32	75	2	109	199	261.5	23.0	89,264	78,138	87.5	5,321
Puerto Rico	--	2	--	2	2	5.9	34.0	1,964	1,518	77.3	252

-- Zero.

1/ Includes white cement plants.

2/ Calculated on a per-kiln basis using 366 days (leap year) minus reported days for routine maintenance and multiplied by the reported unrounded daily capacity.

3/ Includes imported clinker.

4/ Includes one semidry plant.

5/ Data may not add to totals shown because of independent rounding.

TABLE 6
RAW MATERIALS USED IN PRODUCING CLINKER AND CEMENT IN THE UNITED STATES 1/ 2/

(Thousand metric tons)

Raw materials	1999 Clinker	1999 Cement 3/	2000 Clinker	2000 Cement 3/
Calcareous:				
Limestone (includes aragonite, marble, chalk, coral)	91,021	1,138	93,947	1,263
Cement rock (includes marl)	23,981 r/	149 r/	21,820	133
Cement kiln dust 4/	305	112	351	155
Lime 5/	10	46	19	49
Other	--	--	21	225
Aluminous:				
Clay	4,770	23	4,205	8
Shale	3,679	--	3,743	3
Other (includes staurolite, bauxite, aluminum dross, alumina, and other)	387	--	400	--
Ferrous, iron ore, pyrites, millscale, other	1,259	--	1,310	--
Siliceous:				
Sand and calcium silicate	2,959	4	3,142	--
Sandstone, quartzite, other	745	--	925	--
Fly ash	1,521	85	1,679	88
Other ash, including bottom ash	760	--	930	--
Granulated blast furnace slag	--	349	--	303
Other blast furnace slag	97	--	43	--
Steel slag	591	--	805	--
Other slags	45	--	12	10
Natural rock pozzolans 6/	--	16	--	40
Other pozzolans 7/	38	4	38	8
Other:				
Gypsum and anhydrite	--	4,643	--	4,655
Clinker, imported 8/	--	4,607	--	4,573
Other, n.e.c.	--	51	--	46
Total 9/	132,169 r/	11,227 r/	133,391	11,558

r/ Revised. -- Zero.

1/ Includes Puerto Rico.

2/ Nonfuel materials only.

3/ Includes portland, blended, and masonry cements.

4/ Data are probably underreported.

5/ Data are probably underreported on the basis of reported volumes of masonry cements.

6/ Includes pozzolana and burned clays and shales.

7/ Includes diatomite, other microcrystalline silica, silica fume, and other pozzolans, whether or not used as such.

8/ Outside purchases by domestic plants; excludes purchases of domestic clinker.

9/ Data may not add to totals shown because of independent rounding.

TABLE 12--Continued
PORTLAND CEMENT SHIPPED BY PRODUCERS AND IMPORTERS IN THE UNITED STATES, BY DISTRICT 1/ 2/

r/ Revised. W Withheld to avoid disclosing company proprietary data.
1/ Includes imported cement and cement produced from imported clinker.
2/ Includes white cement.
3/ Values represent ex-plant (f.o.b. plant) data collected for total shipments to final customers, not for shipments by specific type of portland cement. Although presented unrounded, the data incorporate estimates for some plants. Accordingly, the data should be viewed as cement value indicators, accurate to no better than the nearest $0.50 or even $1.00.
4/ The district location is that of the reporting facility. Shipments may include material sold into other districts.
5/ Includes shipments by independent importers where district assignation is possible.
6/ Shipments calculated on the basis of an annual survey of plants and importers; may differ from tables 9 and 10, which are based on consolidated company monthly data.
7/ Shipments by importers for which district assignations were not possible.
8/ Data may not add to totals shown because of independent rounding.

TABLE 13
MASONRY CEMENT SHIPPED BY PRODUCERS AND IMPORTERS IN THE UNITED STATES, BY DISTRICT 1/ 2/ 3/

Alaska and Hawaii	3	331	96.98	4	772	214.95
California, Oregon, Washington	469	38,757	82.62	484	43,171	89.19
Independent importers, n.e.c. 8/	39	4,812	122.09	40	6,385	158.79
Total or average 9/	4,338	447,616	103.19	4,275	459,200	107.42

1/ Shipments are to final domestic customers and include shipments of imported cement and cement made from imported clinker.
2/ Includes white cement.
3/ Excludes Puerto Rico (did not record sales of masonry cement).
4/ Values are mill net and represent ex-plant (f.o.b. plant or import terminal) data collected for total shipments to final customers, not for shipments by cement type. Although presented unrounded, the data incorporate estimates for some plants. Accordingly, the data should be viewed as cement value indicators, accurate to no better than the nearest $0.50 or even $1.00 per ton.
5/ The district location is that of the reporting facility. Shipments may include material sold into other districts.
6/ Includes shipments by independent importers where district assignation is possible.
7/ Shipments calculated on the basis of an annual survey of plants and importers; may differ from tables 9 and 10, which are based on consolidated company monthly data.
8/ Shipments by importers for which district assignations were not possible.
9/ Total includes imports shipped by independent importers.

TABLE 14
AVERAGE MILL NET VALUE OF CEMENT IN THE UNITED STATES 1/ 2/

(Dollars per metric ton)

Year	Gray portland cement	White portland cement	All portland cement	Prepared masonry cement	All classes of cement
1999	76.41	166.04	77.18	103.19	76.45 r/
2000	76.61	159.45	77.34	107.42	78.56

r/ Revised.

1/ Excludes Puerto Rico. Mill net value is the actual value of sales to customers, f.o.b. plant or import terminal, less all discounts and allowances, less any freight charges from U.S. producing plant to distribution terminal and to final customers.

2/ Although unrounded, the data incorporate estimates for some plants and are accurate to no better than two significant figures.

-- Zero.

1/ Includes shipments of imported cement and cement ground from imported clinker. Data other than district totals are presented unrounded but incorporate estimates for some plants and are likely accurate to only two significant figures.

2/ District location is that of the reporting facility. Shipments may include material sold into other districts.

3/ Includes shipments by independent importers, where district assignations were possible.

4/ Shipments to concrete product manufacturers include brick-block—6,092; precast—3,127; pipe—1,710; and other or unspecified—2,740.

5/ Shipments to contractors include airport—444; road paving—4,816; soil cement—950; and other or unspecified—1,034.

6/ Shipments to oil well, mining, and waste include oil well drilling—1,168; mining—78; and waste stabilization—160.

7/ Includes shipments for which customer types were not specified.

8/ Shipments calculated based on an annual survey of plants and importers; may differ from tables 9 and 10, which are based on consolidated monthly data.

9/ Data may not add to totals shown because of independent rounding.

10/ Shipments by independent importers for which district assignations were not possible.

TABLE 17–Continued
U.S. EXPORTS OF HYDRAULIC CEMENT AND CLINKER, BY COUNTRY 1/

r/ Revised. -- Zero.
1/ Includes portland and masonry cements.
2/ Free alongside ship (f.a.s.) value. The value of exports at the U.S. seaport or border point of export is based on the transaction price, including inland freight, insurance, and other charges incurred in placing the merchandise alongside the carrier. The value excludes the cost of loading.
3/ Less than 1/2 unit.
4/ Data may not add to totals shown because of independent rounding.

TABLE 22--Continued
U.S. IMPORTS FOR CONSUMPTION OF CLINKER, BY COUNTRY 1/

r/ Revised. -- Zero.
1/ For all types of hydraulic cement. Includes imports into Puerto Rico.
2/ Customs value. The price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import duties, freight, insurance, and other charges incurred in bringing the merchandise to the United States.
3/ Cost, insurance, and freight. The import value represents the customs value plus insurance, freight, and other delivery charges to the first port of entry.
4/ Less than 1/2 unit.
5/ Data may not add to totals shown because of independent rounding.

Source: U.S. Census Bureau.

CHROMIUM

By John F. Papp

Domestic survey data and tables were prepared by Joseph M. Krisanda, statistical assistant, and the world production tables were prepared by Ronald L. Hatch and Glenn J. Wallace, international data coordinators.

In 2000, the U.S. chromium supply (measured in contained chromium) was 139,000 metric tons (t) from recycled stainless steel scrap; 453,000 t from imports; and 924,000 t from Government and industry stocks. Supply distribution was 86,300 t to exports; 840,000 t to Government and industry stocks; and 589,000 t to apparent consumption. Chromium apparent consumption increased by 5.63% compared with that of 1999.

Legislation and Government Programs

The Department of Health and Human Services (HHS) updated the toxicological profile for chromium. HHS revises and republishes toxicological profiles as necessary, but no less than once every 3 years. The profiles are prepared for health professionals and report toxicologic and health effect information (Syracuse Research Corp., 2000).

The Defense Logistics Agency (DLA) disposed of chromium materials under its fiscal year (FY) 2000 (October 1, 1999, through September 30, 2000) Annual Materials Plan (AMP). DLA's FY 2000 AMP (as revised in April) set maximum disposal goals for chromium materials at 90,700 t of chemical grade chromite ore, 227,000 t of metallurgical grade chromite ore, 90,700 t of refractory grade chromite ore, 136,000 t of chromium ferroalloys, and 454 t of chromium metal. DLA also developed its FY 2001 AMP, which set maximum disposal goals of 90,700 t of chemical grade chromite ore; 227,000 t of metallurgical grade chromite ore; 90,700 t of refractory grade chromite ore; 136,000 t of chromium ferroalloys; and 454 t of chromium metal (U.S. Department of Defense, 2001, p. 8, 11).

World Review

Albania.—The Government of Albania (GOA) studied the possibility of privatizing chromite ore mines and ferrochromium smelters (Ryan's Notes, 2000j). GOA contracted Darfo S.p.A. (Italy) to operate the Elbasan ferrochromium smelter. There are two 9 megavoltampere furnaces at the smelter, of which one is producing at the rate of 800 tons per month (t/mo) and the other is closed. Darfo planned to install a 13 megavoltampere and a 25 megavoltampere furnace at a cost of about $15 million, raising the plant's annual production capacity to 40,000 t (Ryan's Notes, 2000a).

Australia.—Danelagh Resources Pty. Ltd. produced chromite at Coobina Chromite Deposit 57 kilometers (km) east-southeast of Newman, Western Australia. The Coobina Range consists of a central core of serpentine. An associated gabbro was formed by the serpentinization of layered peridotite, which contains minor amounts of chlorite, talc, carbonate, chromite, and magnetite. As of December 1997, resources were: measured, 39,000 t graded at 38.5% chromic oxide; indicated, 86,200 t graded at 39.7% chromic oxide; and inferred, 400,000 t of similar grade. Mining process is open cut, and run-of-mine ore is crushed and screened. Danelagh exercised its option to take ownership of the mine leaving Consolidated Minerals

Chromium in the 20th Century

In 1900, "chromic iron ore" was used to describe what we now call chromite ore. Chromium was used as an alloying element, in chemical compounds, and in refractory materials. It played an important role in metallurgy as an alloying element. Chromium and tungsten were being alloyed with iron to make tool steels that permitted large increases in industrial productivity. Chromium was also used to make armor plating hard. These, along with the use of chromite ore as a refractory in steel-producing furnaces, made chromium a critical and strategic material during World War I. In 1900, the United States had resumed production of chromite ore and chromium after a hiatus from 1897 to 1899. Prior to that, the United States had produced 3,767 metric tons of chromite ore in 1890. Production picked up during World War I and again during World War II. In 1900, U.S. chromite ore production was 142 metric tons, which represented 0.27% of world production.

Chromium has played an important role in metallurgy as an alloying element. It was not until 1910 to 1920 that the alloying role of chromium with iron to make stainless steel was developed in France, Germany, the United Kingdom, and the United States. Once this was understood, however, stainless steel became an integral part of the steel industry, accounting for more than 2% of steel production in 2000. Stainless steel manufacture, while small compared with steel production of all grades, nonetheless accounts for about 60% of chromium consumption. Stainless steel, which didn't even exist in 1900, accounted for most of the chromium consumed in 2000, and its share of steel production was growing. Chromium chemical use has grown since 1900; chromite refractory use, however, has been reduced because of technological developments. Superalloys, which are engineering alloys of chromium and nickel used in aggressive environments and were also nonexistent in 1900, were an important strategic use of chromium in 2000, because they were used to make the internal workings of jet engines.

Digitized by Google

Ltd.'s interest to a royalty. Chromite ore production was 6,000 t in 1996; 31,000 t in 1997; 130,000 t in 1998; and 85,000 t in 1999 (Resource Information Unit, 2000, p. 294-295). Danelagh planned to construct a beneficiation plant that would permit it to increase its recoverable resources and to produce more product grades. Danelagh reported proven reserves of 2.2 million tons (Mt) and probable reserves of 10 Mt. The mine produced chromite ore graded at 37% Cr_2O_3 and from 6 millimeters (mm) to 150 mm in size (Ryan's Notes, 2001c).

Tata Iron and Steel Co. Ltd. (India) studied the possibility of constructing a ferrochromium smelter in Gladstone, Queensland. Tata produced chromite ore and ferrochromium in India; however, its ferrochromium production was limited by the availability and cost of electrical power in India. Electrical power was available at a lower cost in Australia than it was in India. A 120,000-ton-per-year (t/yr) capacity ferrochromium smelter with the potential to double that capacity would cost about $50 million (Metal Bulletin, 2000o, 2001; Ryan's Notes, 2001b).

Dragon Mining NL studied the Range Well deposit 67 km northwest of Cue, Western Australia. Chromium occurs predominantly in the iron oxide minerals hematite and goethite. The Range Well laterite resource lies directly over part of a 5.5 km thick funnel-shaped layered ultramafic complex. As of June 1998, inferred resource was estimated at 36 Mt graded at 3.60% chromium (2% cutoff grade) (Resource Information Unit, 2000, p. 295).

Brazil.—Brazil reported production for use in the metallurgical and refractory industries. Brazil produced high- and low-carbon ferrochromium. Brazil reported 1999 chromite ore production of 420,000 t (45.2% Cr_2O_3), exported 194,000 t of chromite ore (53.1% Cr_2O_3), and imported 8,482 t (48.0% Cr_2O_3). In 1999, Brazil produced 91,000 t of chromium ferroalloys of which 71,000 t was high-carbon ferrochromium, 8,200 t was low-carbon ferrochromium, and the remainder was ferrochromium-silicon. Brazil imported 5,000 t of chromium ferroalloys and metal and exported 59 t of ferrochromium (Cesar, 2000).

Associação Brasileira dos Produtores de Ferroligas e de Silício Metálico reported ferrochromium production in 1999 to have been 71,291 t of high-carbon and 7,583 t of low-carbon ferrochromium. Brazil exported 59 t of high-carbon ferrochromium and 168 t of low-carbon ferrochromium. Brazil imported 2,144 t of high-carbon ferrochromium and 2,827 t of low-carbon ferrochromium (TEX Report, 2000r, s, t).

Villa Nova Mine, Amapa State, operated with an annual production capacity of 200,000 t of chromite concentrate from 400,000 t of run-of-mine chromite ore. Villa Nova operated a four-stage beneficiation process that it is replacing with a three-stage spiral separator process having a through-put of 100 metric tons per hour. The new process was expected to achieve a recovery rate of about 96% (Mining Weekly, 2000).

Canada.—Allican Resources planned to build a low-carbon ferrochromium smelter at Thetford Mines, Quebec. The project was estimated to cost about $44.6 million for a 19,000-metric-ton-year smelter. Chromite ore would be supplied initially from imports followed by development of chromite ore deposits in the Thetford area. At this capacity, the plant could supply about one-half of North American low-carbon ferrochromium demand (Ryan's Notes, 2000c).

China.—China reported its national chromium-material trade statistics for 1999. Chromite ore imports were 711,493 t in 1998; 816,229 t in 1999; and 1,112,838 t in 2000. High-carbon ferrochromium exports were 74,849 t in 1997; 65,576 t in 1998; 49,652 t in 1999; and 130,446 t in 2000. Low-carbon ferrochromium exports were 27,220 t in 1997; 36,508 t in 1998; 24,161 t in 1999; and 24,161 t in 2000 (TEX Report, 2000b, c, 2001a, b). Based on this reported trade, apparent consumption of chromium in China was 420,000 t.

The State Economic and Trade Commission of China embarked on a modernization program for the ferroalloys industry. Goals of the plan are to scrap old ferroalloy plants, prohibit construction of new plants, prevent environmental pollution, and promote technology. China operated about 1,600 ferroalloy furnaces of which about 1,000 had electrical power capacity under 3,000 kilovolt-amperes. Electrical furnaces rated under 1,800 kilovolt-amperes were to have been scrapped by the end of 2000; furnaces under 3,200 kilovolt-amperes by the end of 2001. New furnace construction was suspended until 2005 as were expansions. The modernization plan was expected to reduce high-carbon ferrochromium production in China; however, more low-carbon ferrochromium could be produced (TEX Report, 2000d).

European Union.—The European Union (EU) permits duty-free importation of ferrochromium from non-EU countries on a specified amount of material from all non-EU sources. Import duties are applied to imported materials in excess of the specified amount of material. The EU set the duty-free ferrochromium import quota at 1.035 Mt in January 2000 (Metal Bulletin, 2000a). The EU lifted antidumping duties imposed on Kazakhstani and Russian low-carbon ferrochromium producers in 1993 (Metal Bulletin, 2000b). Since the EU made a special trade deal with South Africa, it revised its 2000 duty-free import quota at 515,000 t for South Africa; 520,000 t for all other countries combined. EU left its 2001 duty-free quota for South Africa unchanged while reducing that for all other countries to 400,000 t (Ryan's Notes, 2001c).

Finland.—Outokumpu Polarit Oy planned to merge with Avesta Sheffield (Sweden, United Kingdom). See Sweden section. Outokumpu reported on its ferroalloys production process using preheated charge. Sintered pellets and other charge components are heated before being charged into the smelting furnace (called preheated) on a moving steel belt over which hot gasses from the closed smelting furnace are passed. The system was developed to process chromite ore from Kemi Mine. The process was developed to consume little electrical energy for smelting, have high on-line availability, good working conditions, and adequate environmental aspects (Nurmisalo, 2000). Outokumpu planned the addition of a new melt shop and hot- and cold-rolling facilities that were expected to double output at Tornio works to 800,000 t in 2002.

France.—Delachaux Metals Division produced chromium metal by aluminothermic reduction. Delachaux reported that world demand for chromium metal in 2000 increased to 21,000 t from 20,000 t in 1999. The major end uses for chromium metal were the production of superalloys for use in gas turbine engines or petrochemical production. Delachaux estimated its

Digitized by Google

production in 2000 to be 5,500 t (Metal Bulletin Books, 1995, p. 42; TEX Report, 2000g).

Germany.— ThyssenKrupp Group made a purchase guarantee with SA Chrome and Alloys (South Africa), a startup ferrochromium producer. ThyssenKrupp committed to purchase 230,000 t/yr of high-carbon ferrochromium from SA Chrome and Alloys for 5 years.

India.—The Ministry of Commerce conducted a review of the antidumping duty imposed in January 1997 that found no evidence of injury to domestic industry by the import of low-carbon ferrochromium from Kazakhstan or Russia. Ferro Alloys Corp. Ltd., the only domestic low-carbon ferrochromium producer, has not produced the material for the past 2 years (Metal Bulletin, 2000h; Platt's Metals Week, 2000b).

Ferro Alloys Corp. Ltd. resumed production at Garividi and at Shreeram Nagar. The Garividi plant was closed for financial reasons. The Shreeramnagar plant was closed over a labor dispute. Ferro Alloys Corp. Ltd. exported chromite ore for the first time. Ferro Alloys Corp. Ltd. reported annual ferrochromium production of 87,000 t in 1998 and 51,000 t in 1999. (Metal Bulletin, 2000d, n; TEX Report, 2000f).

Indian Metals and Ferroalloys Ltd. started opencast mining in the Sukinda Valley. Indian Metals and Ferroalloys received 190 hectares (ha) containing 21 Mt of chromite ore reserves when the Government redistributed Sukinda Valley resources in 1999. Chromite ore production reached 31,000 t/mo in May, enough to supply its ferroalloy plants. Indian Metals and Ferroalloys used that chromite ore to feed its ferrochromium smelters at Therubali and Choudwar. At Therubali, Indian Metals and Ferroalloys operated three furnaces electrically rated at 48 megavolt-amperes, 24 megavolt-amperes, and 10 megavolt-amperes. The plant's annual ferrochromium production capacity was 110,000 t; however, Indian Metals and Ferroalloys was producing ferrochromium at the rate of 30,000 t/yr from the 24 megavolt-ampere furnace. Indian Charge Chrome Ltd. was producing ferrochromium at the annual rate of 60,000 t from a 48 megavolt-ampere furnace at Choudwar. Indian Metals and Ferroalloys reported annual production of 56,000 t in 1998 and 67,000 t in 1999 (TEX Report, 2000h).

Jindal Strips Ltd., Ferro Alloys Division planned to exploit chromite ore resources allocated to it when the Government redistributed Sukinda Valley resources in 1999. Jindal planned to produce ferrochromium at the annual rate to 60,000 t at its plant in Andhra Pradesh State (TEX Report, 2000k).

Tata Iron and Steel Co. Ltd. reported 1999 ferrochromium production of 100,000 t and planned to increase that in 2000. Tata produced ferrochromium at its Bamnipal plant in India and under agreements with five other domestic companies operating nine furnaces and five Chinese plants operating seven furnaces. Tata reported 1999 chromite ore production of 772,000 t with plans to increase that to 1,000,000 t by exploiting resources assigned to it when the Government redistributed Sukinda Valley resources in 1999; Tata also reported chromite ore concentrate production of 200,000 t with plans to increase that to 300,000 t. To meet ferrochromium expansion goals, Tata bid to buy Industrial Development Corp.'s ferroalloy plant. To reduce electrical energy cost and assure supply, Tata requested permission to build a powerplant in Orissa. Another plan by Tata to increase ferrochromium production while avoiding the high cost of electrical energy was to build a ferrochromium plant in Australia that would use chromite ore mined by Tata in India (see Australia section) (Lobo, 2000; Metal Bulletin, 2000m, n, p; TEX Report, 2000x).

Iran.—Abdan Ferroalloy Refinery produced ferrochromium with an annual capacity of 15,000 t from a 12.5-megavolt-ampere furnace. The company also operated the Ne'Mat chromite ore mine. The mine's annual production capacity was 400,000 t, some of which was processed in its 120,000-t/yr concentrator.

Iran produced chromite ore in excess of its domestic needs. To increase value added exports, the Government planned to increase domestic annual ferrochromium production to 200,000 t by 2005. New production facilities were planned for the provinces Kerman and Fars. Baft Ferrochrome Industrial Company and Nahid Ehyan Sepahan contracted with ABB Engineering Company (Sweden, Switzerland) to build two plants, each with an annual ferrochromium production capacity of 25,000 t, for $74 million. Construction was expected to take 2 years (Iran Daily, 2000; Ryan's Notes, 2000l).

Japan.—Japan imported 501,727 t of chromite ore; 714,531 t of high-carbon, and 61,796 t of low-carbon ferrochromium; and 3,202 t of chromium metal. Japan produced 131,759 t of high- and low-carbon ferrochromium. Stainless steel production was 3.447 Mt. Ferrochromium imports represented 85% of market share. Japan exported 2,541 t of ferrochromium and 1.162 Mt of stainless steel. Japan had stainless steel scrap imports of 211,581 t and exports to 70,676 t (TEX Report, 2001c, f, g, h, i, j, k).

Based on chromite ore, ferrochromium, chromium metal, and stainless steel scrap trade, chromium apparent consumption in Japan was 586,000 t contained chromium. Japan had a duty-free quota for the importation of ferrochromium amounting to 28,100 t in FY 2000. There was a preferential duty of 3.18% and a temporary duty of 5.3% imposed effective April 1, 2001 (April 1, 2000, through March 31, 2001) (TEX Report, 2001m).

The Ministry of International Trade and Industry reported its intent to review the goals of the rare metals stockpile, which included chromium metal, taking into account current political conditions, budget constraints, and rare metal demand. The rare metals stockpiling program has been active since 1984, at which time chromium was identified as one of the rare metals that would be stocked in the amount necessary to meet 60 days of demand (TEX Report, 2000o). A stockpile equivalent to 78.2% of the goal for chromium had been reached. The review found that the amount of chromium held in the stockpile could be reduced. J S Processing Co. Ltd. is a new business setup in Osaka to supply blended scrap to Nippon Steel Corp. The company is a joint venture among ELG Haniel Metals Corp. (40%), Mitsui and Co. Ltd. (19%), Mitsubishi Corp. (19%), Nippon Steel Trading Co. Ltd. (12%), Fujimoto Kinzoku (5%), and Sangyo Shinko (5%). The company anticipated handling 3,000 t/mo of scrap, of which 1,000 t would be blended (TEX Report, 2000i, j).

High-carbon ferrochromium producers and production in Japan in 2000 were: Nippon Denko Co. Ltd., 7,113 t; NKK Materials Co. Ltd., a subsidiary of NKK Corp., 31,948 t; and Shunan Denko K.K., a subsidiary of Showa Denko K.K.,

Digitized by Google

83,909 t (TEX Report, 2001c).

NKK Materials Co. Ltd. reported the development of a new product, 99.5% pure chromium metal. NKK Materials implemented its two-step electric furnace refining process followed by vacuum degasification at its Toyama plant. NKK expected the chromium metal to be used by master alloy producers for the aircraft industry, a market sector that NKK currently supplies with low-carbon ferrochromium. NKK planned to produce about 1,000 t/yr, developing its chromium metal production capacity to 3,000 t/yr (Metal Bulletin, 2000i; TEX Report, 2000n).

Japan houses about one-fifth of the world's stainless steel industry with a production capacity well in excess of its domestic demand. That industry has participated in the trend to make strategic alliances between ferrochromium consumers, that is themselves, and ferrochromium producers in South Africa. As no new alliances have originated over the past 2 years, that trend appears to have played out. The stainless steel industry itself is now undergoing changes in Japan. From 1961 through 2000, stainless steel production (excluding heat resisting grades) in Japan has grown from 199,462 t to 3,021,080 t, a compounded growth rate of 7.22%. The major stainless steel-producing companies that also operate blast furnaces, their stainless steel production locations, and production in 2000 were Kawasaki Steel Corp., Chiba, 683,858 t; Nippon Metal Industry, Kinuura, 318,888 t; Nippon Steel, Hikari and Yawata, 1,105,318 t; Nippon Yakin Kogyo Co. Ltd., Kawasaki, 337,840 t; Nisshin Steel Co., Shunan, 629,072 t; and Sumitomo Metal Mining Co. Ltd., Wakayama and Naoetsu, 551,672 t. Nippon Steel and Sumitomo agreed to specialize. Nippon Steel was to specialize in producing stainless steel coils; Sumitomo in pipes and shaped steels. Nippon Steel also reached an agreement with Nisshin Steel wherein Nippon Steel would specialize in austenitic (that is, chromium-nickel-containing) grades and Nisshin would specialize in ferritic (that is, chromium-containing) grades. By these agreements, each company expected to benefit economically by producing larger volumes of fewer products and permitting the elimination of excess production capacity (TEX Report, 2000e, 2001d, e). Japan has exported a substantial fraction of its stainless steel production. In recent years, stainless steel production capacity has been developed in Asia, namely in the Republic of Korea and Taiwan. Since new capacity has come into production faster than demand expansion, adjustments are necessary. Capacity reduction takes place where production is least efficient; that is, in older facilities. The older facilities in Asia are in Japan.

Kazakhstan.—Kazchrome was co-owned by Trans World (Alloys) Inc. and the Government of Kazakhstan. A dispute arose in 1997 between Trans World and local company officials over who would control and manage the mine and ferrochromium smelters. The dispute was settled in 2000 when the Chodiev Group (also known as Kazakhstan Mineral Resource Corp.) bought Trans World's interest in the Kazchrome. Kazchrome owns the Donskoy Ore Dressing Complex and the Aksusky Ferroalloy Plant (Aksu) and Aktyubinsk Ferroalloy Plant. Kazchrome was owned by Kazakhstan Mineral Resource Corp. (28.75%), the Kazakhstani Government (31.3%), and holds its own stock (28.75%).

Kazakhstan's chromium industry includes Donskoy Ore Dressing Complex, Aksu, and Aktyubinsk Ferroalloy Plant. Donskoy extracted chromite ore from the Poiskovy open pit and the Molodyonzhnaya underground mines (TEX Report, 2000m). Donskoy completed construction of equipment that will produce briquettes from chromite ore fines, with an annual capacity of 500,000 t (TEX Report, 2001l). Aksu installed a new 64-megavolt-ampere furnace manufactured by Mannesmann-Demag (Germany) that has a high-carbon ferrochromium production capacity of 102,000 t/yr. Aksu planned to add about 160,000 t of high-carbon ferrochromium production capacity in the form of two 50-megavolt-ampere or three 30-megavolt-ampere furnaces in 2002 (Ryan's Notes, 2000e; TEX Report, 2000l).

Norway.—Elkem ASA produced high-carbon ferrochromium containing 60% to 65% chromium from two closed furnaces at its ferrochromium plant in Rana. Annual production capacity was 160,000 t (Ryan's Notes, 2000h).

Philippines.—The four ferrochromium producers in the Philippines were reported to have ceased production several years ago (Bennet, Barrand, and Clarkson, 2000). Benguet Corporation mined foundry and refractory grades of chromite ore at Masinloc Chromite Operation in Zambales Province. Having developed a stockpile equivalent to 15 to 18 months of consumption, Benguet temporarily suspended production in 1999 to reduce stocks (Industrial Minerals, 1999). Having depleted its stockpile, Benguet started underground chromite ore mine production (Platt's Metals Week, 2000a).

Russia.—Serov Ferroalloy Plant reported production of 129,500 t of ferrochromium in 1999: 90,000 t of high-carbon ferrochromium; 18,500 t of medium-carbon ferrochromium; and 21,000 t of low-carbon ferrochromium. The plant is 359 km from Sverdlovsk. It uses locally mined and imported chromite ore. Serov was developing a new mine at Salechard, which it expected to yield chromite ore of higher grade than that currently available from local sources. Serov imported ore from Kazakhstan and Turkey (Metal Bulletin, 2000k).

Severonickel Combine, a subsidiary of RAO Norilsk Nickel, continued development of the Sopcheozero chromite deposits. Norilsk sought a partner to develop the chromite ore mine and a ferrochromium smelter (Ryan's Notes, 2000b).

Chelyabinsk Electrometallurgical Integrated Plant produced low-carbon ferrochromium with an annual production capacity of 144,000 t. Chelyabinsk imported its chromite ore from Kazakhstan (Ryan's Notes, 2001a). Chelyabinsk planned to install a scrap recycling circuit (Ryan's Notes, 2000g).

South Africa.—The Minerals Bureau reported that, from a reserve base of 3,100 Mt of chromite ore, in 1999 South Africa produced 6,817,000 t of chromite ore from which it produced 2,155,000 t of ferrochromium and other products. South Africa exported 841,000 t of chromite ore and 1,897,100 t of ferrochromium in 1999 (Armitage, 2000). Based on chromite ore production and chromite ore and ferrochromium trade, 1999 South African chromium apparent consumption was 755,658 t, contained chromium. The Minerals Bureau reported chromite ore production in 2000 of 6,620,754 t and sales of 6,744,278 t. Eighty-five percent of sales was sold locally; the remaining 15% was exported (South African Minerals Bureau, 2001).

South Africa considered changing its mining law. Currently,

Digitized by Google

companies own mineral property rights. Draft legislation would change to government ownership of minerals and government licensing of mining for a specified period of time (Ryan's Notes, 2000h, k). Eskom, the South African power company, planned to change its billing structure for the ferrochromium industry, as their current 7-year contract with that industry comes to a close. The current contract adjusts the price of electrical energy between minimum and maximum rates based on the price of ferrochromium. The proposed system would be a fixed tariff rate of 12.2 cents per kilowatthour. Eskom was the fifth largest electrical power producer worldwide and planned to be privatized (Metal Bulletin, 2000l; Ryan's Notes, 2000f, 2001d). South African environmentalists made their desire for stricter pollution-control standards known at public hearings held to discuss the environmental impact of new plants or new furnaces (Ryan's Notes, 2000m).

ASA Metals (Pty.) Ltd. planned another furnace and an agglomeration facility for its ferrochromium plant near Burgersfort, Northern Province. ASA completed construction and started production at its ferrochromium plant last year. ASA had an annual ferrochromium production capacity of 60,000 t from a 33 megavolt-ampere furnace. ASA is a joint venture between Northern Province Development Corporation (40%) and East Asian Metals Investment Co. Ltd. (60%) (Lourens, 2000).

South Africa Chrome and Alloys Ltd. (SAChrome), formerly Southern Witwatersrand Exploration Co., studied the feasibility of constructing a ferrochromium plant. The plant was to use chromite ore from its Horizon and Chromeden mines. SAChrome planned to build a pelletizing and sintering plant with an annual capacity of 520,000 t and a ferrochromium plant with annual production capacity of 230,000 t. They planned two closed furnaces with electrical capacity of 54 megavolt-amperes each. The plant was to be located near Boshoek at a rail siding about 40 km from the mine and about 650 km from Richards Bay. Plant cost was estimated at about $100 million. SAChrome planned to use chromite ore from the UG-2 and LG-6 seams to produce ferrochromium containing 51% chromium. Thyssen Krupp Metallurgie contracted to take up to 250,000 t/yr of ferrochromium for 5 years from SAChrome (Graulich, 2000; Ryan's Notes, 2000d, m, 2001b).

Associated Manganese Mines of South Africa Ltd. (Assmang) started production at the Dwarsrivier chromite ore mine in Mpumalanga Province about 30 km from Steelpoort (Mining Journal, 2000b). The opencast mine and beneficiation plant located at the mine site had an annual production capacity of about 350,000 t/yr. Assmang planned to start underground mining in 2001, thereby bringing production capacity up to about 1 million tons per year. The LG-6 seam, which dips at 8 degrees to 14 degrees and has a thickness of about 180 centimeters, was being mined. Within the mine, ore was transported by conveyor belt from the pit to the beneficiation plant. From the plant, ore was trucked to the Steelpoort rail terminal from which it was carried by train the remaining 60 to 65 km to Feralloys, Assmang's ferrochromium plant at Machadodorp (http://www.avmin.co.za/mediashop/pressreleast.asp?story=5, downloaded April 13, 2000) (TEX Report, 2000a). Feralloys operated three furnaces and a metal-from-slag recovery process. The furnaces accounted for an annual ferrochromium production capacity of about 125,000 t; the metal-from-slag recovery was 25,000 t. Two of their three furnaces had electrical capacity of 24 megavolt-amperes; the third furnace, 30 megavolt-amperes. The two 24-megavolt-ampere furnaces were upgraded to 30 megavolt-amperes, bringing Feralloys' ferrochromium production capacity up to 175,000 t/yr (Metal Bulletin, 2000g). A fourth furnace and pelletizing plant of Outokumpu technology was planned. The fourth furnace was planned to have an electrical capacity of 54 megavolt-amperes and ferrochromium production capacity of 130,000 t/yr. The pelletizing plant was planned to produce 350,000 t/yr of pellets (Metal Bulletin, 2000f).

Columbus Stainless Steel estimated its production of stainless steel flat products to have been 440,000 t in 2000, of which 105,000 t was sold domestically (Metal Bulletin, 2000c).

Hernic (Pty.) Ltd. brought its third furnace into production. The third furnace is supported by pelletizing and preheating operations manufactured by Outokumpu Oy (Finland). The system was installed at a cost of about 200 million Rand and increased Hernic's annual ferrochromium production capacity to 260,000 t (Venter, 2000b).

Samancor Ltd. planned a greenfield ferrochromium plant in the western belt of the Bushveld Complex near its Mooinooi Mine. Samancor planned to construct two closed furnaces to be fed by one pelletizing and sintering plant on a 50-ha site at a cost of 500 million Rand. Production technology is from Outokumpu Technology (Finland) that Samancor is using at its Ferrometals plant. This will be Samancor's first ferrochromium plant in the western belt of the Bushveld complex. The mine was expected to produce about 760,000 t/yr of chromite ore. The smelter was expected to produce 520,000 t/yr of preheated pellets, from which about 300,000 t/yr of ferrochromium would be produced. The plans were reported to have included the use of UG-2 chromite byproduct from platinum mining and iron and steel scrap (Venter, 2000a). Samancor anticipated proceeding with plant construction when market conditions indicated the need for this new plant (Gonsalves, 2000).

Xstrata S.A. (Pty.) Ltd. was developing the Townlans Mine in the Rustenburg area, western belt of Bushveld Complex. The mine was expected to start production in 2001 and have a production capacity of 480,000 t/yr. The new mine complements Xstrata's existing mines in the western belt: Waterval, 273,000 t/yr production capacity and Kroondal Mine, 663,000 t/yr; and the Thorncliffe Mine, 1,056,000 t/yr in the eastern belt (TEX Report, 2000y).

Samancor and Xstrata formed an equally owned joint venture to develop chromite ore mining and ferrochromium production in the Rustenburg area of the western belt of the Bushveld Complex. The joint venture will develop chromite ore reserves owned by Samancor that are accessable via Xstrata's Kroondal Mine and will expand Xstrata's Wonderkop smelter. The Wonderkop smelter near Rustenburg had an annual ferrochromium production capacity of about 300,000 t from four, 39 megavolt-ampere furnaces, two pelletizing lines, and a recovery plant. Wonderkop obtained its chromite ore supply primarily from the Kroondal Mine. Samancor and Xstrata planned to add two 45 megavolt-ampere furnaces, pelletizing and prereduction, and metal-from-slag recovery at a cost of

Digitized by Google

about $40 million. The new production equipment will add 180,000 t/yr of ferrochromium to the plant's annual production capacity. Additional chromite ore supplies will come through development of the Kroondal Mine to exploit reserves owned by Samancor. Production was expected to start in 2001 (Metal Bulletin, 2000j; Mining Journal, 2000a; Platt's Metals Week, 2000c; Robinson, 2000b; Ryan's Notes, 2000i; TEX Report, 2000p).

Sweden.—Vargön Alloys AB planned to purchase a recovery plant that would recover ferrochromium from slag. The plant was planned to process slag at the rate of 100 metric tons per hour. The equipment supplier was Apic Toll Treatment, a joint venture between Mintek and Bateman Titaco Company (Robinson, 2000a).

The European stainless steel producers Avesta Sheffield Ltd. (Sweden, United Kingdom) and Outokumpu Polarit Oy (Finland) merged to form AvestaPolarit Abp. Avesta Sheffield is the result of the merger of Avesta (Sweden) and British Stainless Steel (UK) in 1992. The merger was to be effected in 2001. The new company would have a stainless steel production capacity of 1.7 Mt. Other stainless steel producers in Europe include Acciai Speciali Terni SpA (Italy), Acerinox SA (Spain), ALZ NV (Belgium), Ugine SA (France), and Krupp-Thyssen Nirosta GmbH (Germany). Raw materials supply appears to favor Outokumpu Polarit's plant at Tornio because it is near to chromium and nickel supply (Metal Bulletin Books, 1995, p. 4, 18, 30, 48, 79, 96; Avesta Sheffield, 2000; TEX Report, 2000q).

Taiwan.—Taiwan reported production of ferrochromium to have been 296,297 t high carbon in 1998; 387,995 t high carbon in 1999; and 380,996 t high carbon, and 14,175 t low carbon in 2000 (TEX Report, 2001n, o). Taiwan reported stainless steel scrap imports of 20,789 t in 2000 (TEX Report, 2000v). Taiwan reported stainless steel scrap exports of 45,095 t in 1998 and 49,055 t in 1999 (TEX Report, 2000u).

Tang Eng Iron Works, Yieh United Steel, Walsin Carteck, and China Steel Corp. produced about 1.2 Mt of stainless steel in 2000 (TEX Report, 2000w).

Turkey.—Eskikaya and Aydiner (Eskikaya and Aydiner, 2000) reported that Turk Maadin A.S. operated the Dagardi, Kavak, Koycegiz, and Tavas chromite ore mines. The Kavak Mine had 2 Mt of reserves, and annual production was about 100,000 t. Eskikaya reported that mine performance was improved when they introduced new mining techniques and equipment. In particular, the improvements reduced accidents, manpower required, and timber consumption. These savings could extend the reserves and mine life by making low-grade ore production economical.

Zimbabwe.—Zimbabwe Alloys Ltd. reported production of 33,425 t of low-carbon ferrochromium in 1999. Zimbabwe Alloys renovated its Gweru plant. It converted one 28-megavolt-ampere furnace from the production of ferrochromium-silicon to the production of high-carbon ferrochromium. The conversion cost about $3 million. The new furnace had a high-carbon ferrochromium production capacity of 35,000 t/yr. Zimbabwe Alloys will continue to produce low-carbon ferrochromium under a joint-venture agreement with Japan Metals and Chemicals Co. (Japan) (Ryan's Notes, 2000n).

Current Research and Technology

Mintek found that dry milling of ferrochromium slag or chromite ore produces a buildup of chromium in the +6 valence state. Chromium in chromite ore is in the +3 valence state. Mintek found that longer duration milling resulted in higher concentration of chromium in the +6 valence state (Mintek Bulletin, 2000).

Outlook

The outlook for chromium consumption in the United States and the rest of the world is about the same as that for stainless steel, which is the major end use for chromium worldwide. Thus, stainless steel industry performance largely determines chromium industry demand worldwide. (See the following section on stainless steel.)

Several trends are occurring simultaneously in the chromium industry. Chromite ore production is moving from independent producers to vertically integrated producers. In other words, chromite ore mines tend to be owned and operated by ferrochromium or chromium chemical producers. This trend is associated with the migration of ferrochromium production capacity from stainless steel-producing countries to chromite ore-producing countries. As ferrochromium-production capacity is rationalized in historically producing countries, which are usually stainless steel producing countries, new furnaces or plants are constructed in chromite ore producing areas. The electrical power capacity and production capacity of submerged-arc electric furnaces used to produce ferrochromium has been increasing. Production process improvements such as agglomeration of chromite ore, preheating and prereduction of furnace feed, and closed furnace technology have been retrofitted at major producer plants and are being incorporated into newly constructed plants. When ferrochromium plants started to be built, furnaces rated in the low kilovoltampere range were common. Furnaces built recently tend to approach the mid megavolt-ampere range. The introduction of post melting refining processes in the steel industry after 1960 started a shift in consumption from low-carbon ferrochromium to high-carbon ferrochromium causing a decline in low-carbon ferrochromium production that continues today. After years of ferrochromium production, slag stockpiles have built up. Recently developed processes efficiently recover ferrochromium from that slag. Equipment to use these processes was being installed at plant sites. In South Africa, the major chromite ore- and ferrochromium-producing country, two trends are emerging; ferrochromium plants are being developed in the western belt of the Bushveld Complex, and chromite ore byproduct from platinum operations are being accommodated by new production processes. After many years of stainless steel production, stainless steel scrap resources have accumulated. Stainless steel producers have been improving their production processes by reducing scrap generated during the production process and by increasing the amount of scrap used as feed material. As a result, the fraction of stainless steel scrap use as feed material has been increasing, especially from post consumer sources.

SALIENT CHROMIUM STATISTICS 1/

(Metric tons, contained chromium, unless otherwise specified)

		1996	1997	1998	1999	2000
Stainless steel (gross weight)--Continued:						
Scrap:						
Receipts		579,000	705,000 r/	610,000 r/	694,000 r/	817,000
Consumption		1,040,000	1,140,000	1,040,000	1,140,000	1,220,000
Exports		303,000	370,000	298,000	260,000	468,000
Imports		50,500	64,100	57,200	66,100	56,200
Value of trade:						
Exports	thousands	$583,000	$653,000	$622,000	$628,000	$782,000
Imports	do.	$1,880,000	$1,720,000	$1,680,000	$1,560,000	$2,010,000
Scrap exports	do.	$234,000	$231,000	$176,000	$151,000	$310,000
Scrap imports	do.	$28,500	$33,700	$21,600	$27,700	$35,500
Net exports 11/ 14/	do.	($1,090,000)	($870,000)	($903,000)	($811,000)	($955,000)

e/ Estimated. r/ Revised. NA Not available. W Withheld to avoid disclosing company proprietary data. -- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Calculated assuming chromite ore to average 44% Cr_2O_3, which is 68.42% chromium.
3/ Calculated assuming chromium content of ferrochromium to average 57%.
4/ Calculated assuming chromium content of stainless steel to average 17%.
5/ Industry stocks include chromium ferroalloy and metal producer stocks before 1998; and chromite ore consumer stocks before 2000.
6/ Includes chromium ferroalloys and metal and other chromium materials in the United States.
7/ Time-weighted average price of South African chromite ore, as reported in Platt's Metals Week.
8/ Time-weighted average price of imported high-carbon chromium that contains 50% to 55% chromium, as reported in Platt's Metals Week.
9/ Time-weighted average price of electrolytic chromium metal, as reported in American Metal Market.
10/ Includes chromite ore and chromium ferroalloys, metal, and chemicals.
11/ Data indicate that imports are greater than exports.
12/ Data on stainless steel production from American Iron and Steel Institute Annual Reports and quarterly production of stainless and heat-resisting raw steel.
13/ Data on stainless steel shipments from American Iron and Steel Institute Annual Reports.
14/ Includes stainless steel and stainless steel scrap.

TABLE 2
PRINCIPAL U.S. PRODUCERS OF CHROMIUM PRODUCTS IN 2000, BY INDUSTRY

Industry and company	Plant
Metallurgical:	
Eramet Marietta Inc.	Marietta, OH.
JMC (USA) Inc.	Research Triangle Park, NC.
Refractory:	
National Refractories and Minerals Corp.	Moss Landing, CA, and Columbiana, OH.
RHI Refractories America Inc.	Womelsdorf, PA.
Chemical:	
Elementis Chromium LP	Corpus Christi, TX.
Occidental Chemical Corp.	Castle Hayne, NC.

TABLE 3
U.S. CONSUMPTION OF CHROMIUM FERROALLOYS AND METAL, BY END USE 1/

(Metric tons, gross weight, unless noted)

End use	Ferrochromium		Ferrochro-mium silicon	Other	Total

r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified." -- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Contains less than 3% carbon.
3/ Contains 3% or more carbon.
4/ Withheld to avoid disclosing company proprietary data.
5/ Includes structural and hard-facing welding material.
6/ Includes cutting materials and magnetic, aluminum, copper, nickel, and other alloys.
7/ Includes estimates.
8/ Includes 4,670 tons of chromium metal.
9/ Includes 195 tons of chromium metal.
10/ Includes 4,690 tons of chromium metal.
11/ Includes 245 tons of chromium metal.
12/ Includes 4,980 tons of chromium metal.
13/ Includes 191 tons of chromium metal.

TABLE 4
U.S. GOVERNMENT STOCKPILE YEAREND INVENTORIES AND CHANGE FOR CHROMIUM-CONTAINING MATERIALS 1

(Metric tons, gross weight)

TABLE 5
TIME-VALUE RELATIONS FOR CHROMITE ORE, FERROCHROMIUM, AND CHROMIUM METAL 1/ 2.

(Annual average value, dollars per metric ton)

Material	1999		2000	
	Contained chromium	Gross weight	Contained chromium	Gross weight
Chromite ore:				
Not more than 40% chromic oxide	215	65	841	210
More than 40%, but less than 46% chromic oxide	866	266	178	56
46% or more chromic oxide	181	62	191	62
Average 3/	184	62	198	64
Ferrochromium:				
Not more than 3% carbon:				
Not more than 0.5% carbon	XX	XX	1,090	707
More than 0.5%, but not more than 3% carbon	XX	XX	1,540	1,000
Average 3/	1,560	1,040	1,470	956
More than 3%, but not more than 4% carbon	572	372	--	--
More than 4% carbon	658	387	710	409
Average 3/	723	429	797	466
Chromium metal	XX	6,270	XX	5,980

XX Not applicable. -- Zero.
1/ Based on Customs value of chromium contained in imported material.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.
3/ Mass-weighted average.

TABLE 6
PRICE QUOTATIONS FOR CHROMIUM MATERIALS AT BEGINNING AND END OF 2000 1/

Material		January	December	Year average 2/
Chromite ore:				
South Africa	dollars per metric ton	60- 65	NA	NA
Turkey	do.	140-150	NA	NA
High-carbon ferrochromium, imported:				
50% to 55% chromium	cents per pound of chromium	37.00-40.00	39.00-41.00	41.44
60% to 65% chromium	do.	38.00-40.50	37.00-39.00	40.13
Low-carbon ferrochromium, imported:				
0.05% carbon	do.	67-70	60-65	69
0.10% carbon	do.	53-54	47-50	57
Chromium metal, domestic:				
Electrolytic, standard	cents per pound	415-470	435-445	443
Electrolytic, vacuum	do.	525-550	520-565	542

NA Not available.

TABLE 10
U.S. IMPORTS FOR CONSUMPTION OF CHROMIUM MATERIALS, BY TYPE 1/

HTS 2/	Type	1999 Quantity (kilograms)	1999 Value (thousands)	2000 Quantity (kilograms)	2000 Value (thousands)	Principal sources, 2000
	Metals and alloys:					
	Chromium metal:					
8112.20.3000	Waste and scrap, gross weight	17,800	$150	40,700	$598	Russia (30%); United Kingdom (26%); Netherlands (13%); China (12%); Germany (12%); Singapore (5%); Mexico (1%).
8112.20.6000	Other than waste and scrap, gross weight	9,010,000	56,400	9,900,000	58,800	China (25%); Russia (25%); France (24%); United Kingdom (21%); Kazakhstan (2%); Germany (1%).
7202.50.0000	Ferrochromium-silicon, gross weight	36,000,000	18,700	20,700,000	10,300	Kazakhstan (46%); Russia (30%); Zimbabwe (18%); South Africa (6%).
7202.50.0000	Ferrochromium-silicon, contained weight	12,700,000	--	7,670,000	--	
	Chemicals (gross weight):					
	Chromium oxides and hydroxides:					
2819.10.0000	Chromium trioxide	6,730,000	12,000	8,030,000	13,700	Kazakhstan (68%); China (11%); Turkey (10%); Italy (5%); Poland (2%); Japan (1%); United Kingdom (1%).
2819.90.0000	Other	4,300,000	14,800	3,220,000	12,100	Japan (28%); China (25%); Germany (25%); United Kingdom (10%); Poland (4%); Netherlands (3%); Austria (2%); Belgium (1%); Colombia (1%); France (1%); Turkey (1%).
2833.23.0000	Sulfates of chromium	391,000	386	239,000	227	United Kingdom (46%); Mexico (30%); Poland (15%); Argentina (8%); Germany (1%).
	Salts of oxometallic or peroxometallic acids:					
2841.20.0000	Chromates of lead and zinc	159,000	355	289,000	563	Norway (38%); Canada (23%); Korea, Republic of (21%); China (9%); United Kingdom (6%); Japan (3%).
2841.30.0000	Sodium dichromate	10,400,000	7,770	16,900,000	10,500	United Kingdom (98%); China (2%).
2841.40.0000	Potassium dichromate	177,000	329	205,000	392	United Kingdom (45%); India (20%); Kazakhstan (20%); Netherlands (10%); Canada (5%); Japan (1%).
2841.50.0000	Other chromates and dichromates; peroxochromates	471,000	1,050	56,900	183	Korea, Republic of (49%); Austria (30%); United Kingdom (20%); India (2%).
2849.90.2000	Chromium carbide	252,000	2,870	182,000	2,010	Japan (48%); Germany (37%); United Kingdom (12%); Canada (2%); Austria (1%).
	Pigments and preparations based on chromium (gross weight):					
3206.20.0010	Chrome yellow	6,760,000	19,000	7,000,000	18,700	Canada (54%); Korea, Republic of (11%); Mexico (11%); Hungary (9%); China (8%); Colombia (4%); Japan (1%).
3206.20.0020	Molybdenum orange	1,550,000	6,600	1,620,000	7,110	Canada (87%); Mexico (6%); Philippines (3%); China (1%); Colombia (1%); Germany (1%); Hungary (1%); Japan (1%).
3206.20.0030	Zinc yellow	34,000	32	19,000	21	Brazil (89%); Colombia (5%); Italy (5%).
3206.20.0050	Other	1,250,000	4,330	1,530,000	6,290	China (39%); France (39%); Germany (10%); Canada (4%); Poland (2%); Belgium (1%); Japan (1%); Korea, Republic of (1%); Switzerland (1%); United Arab Emirates (1%).

e/ Estimated. r/ Revised. NA Not available. XX Not applicable. -- Zero.

1/ Chromite ore production was reported by country starting in the 1911 Chromite Minerals Yearbook Chapter (reporting production for the years 1906 through 1910) when production was reported in metric tons. Chromite ore production by country has since been reported continually in the Chromite Minerals Yearbook chapters through 1946 and in its successor, the Chromium Minerals Yearbook chapters since 1947. In the 1958 Chromium Minerals Yearbook chapter, chromite ore production by country was reported in units of short tons for the 1900 through 1958 time period. From 1959 through 1970, chromite ore production by country was reported in short tons. From 1971 through 1987, chromite ore production by country was reported in thousand short tons. Since 1988 (1984 year-of-data), chromite ore production has been reported in metric tons. Country chromite ore production data presented here are those reported in the Minerals Yearbook chapters converted from short to metric tons where necessary and rounded to thousand tons from 1969 through 1983, and rounded to no more than three significant digits from 1900 through 1968 and from 1984 through 1995. Since unrounded data were not available before 1996, world production was computed from country production converted in units but not yet rounded; world production was then rounded to no more than three significant digits. From 1996 through 2000, chromite ore world production and estimated country production were rounded to no more than three significant digits. From 1996 through 2000 chromite ore world production and estimated country production were rounded to no more than three significant digits. Chromite ore production by country from 1900 through 1949 came from the 1958 chapter review; the remainder, from chromium chapters.

2/ Figures for all countries represent marketable output unless otherwise noted.

3/ Direct shipping plus concentrate production from 1995 through 2000.

4/ Average Cr_2O_3 content was as follows: 1996--42.2%; 1997--37.4%; 1998-99--45% (revised); and 2000--45%.

5/ Less than 500 short tons.

6/ Production estimates as exports from 1950 through 1960.

7/ Egypt reported as United Arab Republic from 1956 through 1961.

8/ Kazakhstan formerly part of the U.S.S.R. from 1900 through 1991.

9/ Reported figure.

10/ Macedonia reported as Yugoslavia from 1900 through April 1992.

11/ Madagascar reported as Malagasy or Malagasy Republic from 1950 through 1974.

12/ Pakistan reported with India from 1900 through 1946.

13/ Russia reported as the U.S.S.R. from 1900 through 1991.

14/ South Africa reported as the Union of South Africa from 1900 through 1957.

15/ The U.S.S.R. dissolved in December 1991.

16/ Reported as North Vietnam from 1959 through 1961.

17/ Yugoslavia part of Austria-Hungary from 1900 through 1917; Kingdom of the Serbs, Croats and Slovenes from 1918 through 1928. Dissolved in April 1992.

18/ Zimbabwe reported as Southern Rhodesia from 1900 through 1950 and 1960 through 1975, and as Federation of Rhodesia and Nyasaland from 1951 through 1959.

19/ Production not reported by country includes data from Afghanistan, Argentina, Brazil, Bulgaria, Canada, Guatemala, Indochina, Lebanon, Mexico, Norway, Portugal, Romania, Sweden, and the United Kingdom from 1900 through 1949; Bulgaria and Romania from 1950 through 1962; and North Vietnam for 1962.

e/ Estimated. r/ Revised. NA Not available. W Withheld to avoid disclosing company proprietary data. XX Not applicable. -- Zero.

1/ Ferrochromium production was reported by country starting in the 1976 Ferroalloys Minerals Yearbook Chapter (data series starting in 1974) as part of the world ferroalloy production table. Ferrochromium production was reported in units of thousand short tons from the 1976 chapter through the 1989 chapter. In the 1990 Ferroalloys Minerals Yearbook Chapter (1986 data), reporting units changed to metric tons. Ferrochromium production by country was added to the Chromium Minerals Yearbook Chapter in 1988 where production was reported for 1988 as thousand metric tons. Reporting ferrochromium production by country in the Chromium chapter lapsed for 2 years after which it was reintroduced in 1991 as a 5-year table (first year-of-data 1987) in units of metric tons. Ferrochromium production by country has since been reported in the Chromium chapter. In 1994, a policy of rounding data to no more than three significant digits was implemented. The policy applies to published data such as production for a specific country for a specific year. Information computed from that data, such as world production, is to be computed from unrounded data. Country ferrochromium production data presented here is that reported in the Minerals Yearbook Chapters converted from short to metric tons where necessary and rounded to thousand metric tons from 1974 through 1985 and rounded to no more than three significant digits from 1986 through 1995. Since unrounded data were not available before 1996, world production was computed from country production converted in units but not yet rounded; world production was then rounded to no more than three significant digits. From 1996 through 2000 ferrochromium world production, U.S. production, and estimated country production were rounded to no more than three significant digits.

2/ Croatia and Macedonia reported as part of Yugoslavia from 1974 through 1991.

3/ Includes high- and low-carbon ferrochromium.

4/ Reported figure.

5/ Czechoslovakia dissolved on December 31, 1992.

6/ Reported as East and West or Democratic and Federal Republic of Germany from 1974 through 1990.

7/ Undistributed.

8/ Includes ferrochrome and charge chrome.

9/ Kazakhstan and Russia reported as part of the U.S.S.R. from 1974 through 1991.

10/ Slovakia reported as part of Czechoslovakia from 1974 through 1992; Slovenia reported as part of Czechoslovakia from 1974 through 1991.

11/ Zimbabwe reported as Southern Rhodesia from 1974 through 1976.

12/ Includes high- and low-carbon ferrochromium and ferrochromium silicon.

13/ The U.S.S.R. disolved in December 1991.

14/ Yugoslavia dissolved in April 1992.

15/ Includes high- and low-carbon ferrochromium, ferrochromium silicon, chromium metal, and other chromium materials.

CLAYS

By Robert L. Virta

Domestic survey data and tables were prepared by Maria Arguelles, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

The amount of clay sold or used by domestic producers in 2000 was 40.8 million metric tons (Mt) valued at $1.52 billion, a decrease of 3% in tonnage and value from that of 1999. Production of fire clay and fuller's earth increased, but production of ball clay, bentonite, common clay and shale, and kaolin decreased. Of the clay and shale produced in 2000, common clay and shale accounted for 58% of the tonnage, and kaolin accounted for 61% of the value. Imports of clays increased to 95,500 metric tons (t) valued at $34.9 million. Exports increased to 5.26 Mt valued at $896 million (table 1).

Legislation and Government Programs

The U.S. Environmental Protection Agency continued its work on the maximum achievable control technology (MACT) emission standards for the clay processing and manufacturing industries. The MACT standards are required under the National Emissions Standards for Hazardous Air Pollutants Program, which was established by the 1990 Amendments to the Clean Air Act. The MACT standards cover clay processors and manufacturers of lightweight aggregate, brick and structural clay products, and ceramics. The agency will issue MACT standards for each category because each has different emissions, emission controls, and economic considerations (American Ceramic Society Bulletin, 2000).

The U.S. Food and Drug Administration (FDA) clarified its guidance document for dioxins in anticaking agents, including clay, used in animal feeds. At issue was the use of the terms "mined clay products" and "lime" in the guidance document. In the first case, nonclay anticaking agents also were covered. In the later, limestone rather than lime was covered. The wording was changed to "clay and nonclay anticaking agents" to avoid any confusion, and the FDA urged the animal feed industry to develop a more scientifically accurate naming scheme for its products to avoid confusion in the future (U.S. Food and Drug Administration, 2000).

Clay mining has an environmental impact because of the disturbance to the land. Overburden is moved, and clays are removed, leaving a depression or pit. State laws usually require leveling or contouring of the disturbed area and planting trees or grasses to prevent or minimize erosion. For processing, the impoundment of slimes and dust control are usually required. The rules for disposal of coarse tailings are similar to or included within those laws governing reclamation of the mined area.

Production

In 2000, 228 companies operated approximately 640 clay and shale pits or quarries. The largest 20 companies, many with multiple operations, accounted for 50% of the tonnage and 79% of the value for all types of clay produced and sold or used. Clay production was reported in all States except Alaska, Delaware, Hawaii, Idaho, New Hampshire, Rhode Island,

Clay and Shale in the 20th Century

By 1900, the domestic clay and shale industry was fairly well established. Production of all clay types was about 1.1 million metric tons per year; fire clay accounted for 69% of the clay and shale produced in the United States, followed by common and miscellaneous clays, 18%; stoneware clay, 9%; kaolin, 2%; ball clay, 1%; and fuller's earth, 1%. In the early 1900s, the major clay markets were fire brick and refractory mortars. Other large markets included brick, drain tile, sewer tile, and structural tile for both fire clay and common clay. Markets for the other clay types were much smaller. Major uses for ball clay were in ceramics. The major market for bentonite was foundry sand bond. Decolorizing oils and greases applications were major applications for bentonite and fuller's earth. Paper and ceramics were the major markets for kaolin. Fire clay production continued to dominate until the 1940s when it was surpassed by common clay and shale. Despite this, the time period between 1945 and 1970 were the boom years for fire clay. In contrast to the production of common clay and shale and fire clay, production of ball clay, bentonite, fuller's earth, and kaolin increased at a relatively steady pace from 1900 onward.

In 2000, domestic production of clays was 40.7 million tons. Common clay and shale accounted for 58% of production, followed by kaolin, 22%; bentonite, 9%; fuller's earth, 7%; ball clay, 3%; and fire clay, 1%. Major uses for ball clay in 2000 were ceramic tile (35%) and sanitaryware (22%); foundry sand bond (28%), pet waste absorbent (23%), drilling mud (17%), and iron ore pelletizing (13%) for bentonite; brick (56%), cement (17%), and lightweight aggregate (16%) for common clay and shale; refractories (73%) for fire clay; absorbents (75%) for fuller's earth; and paper (61%) and refractories (11%) for kaolin. In general, variations in sales of clay and shale tracked the rise and fall of the U.S. economy because much of the clay tonnage was associated with construction. A few specific factors that affected sales of clay and shale were increased oil drilling in the 1920s and its decline in the late 1980s, the Great Depression of the 1930s, changes in refractory demands beginning in the 1960s, decreased use of brick in housing beginning in the late 1970s, the energy crisis of the 1970s, and the popularity of clumping pet waste absorbents and the intrusion of precipitated calcium carbonate into the domestic paper market in the 1990s.

Digitized by Google

Vermont, Wisconsin, and the District of Columbia (table 2). For States not reporting production, clay probably was extracted for construction uses by companies not participating in the U.S. Geological Survey (USGS) canvass of the clay and shale industry.

The 10 leading producer States, in decreasing order by tonnage, were Georgia, Wyoming, Alabama, Texas, North Carolina, Missouri, Ohio, South Carolina, California, and Virginia. The 10 leading producing companies, in alphabetical order, were American Colloid Co. (bentonite); Engelhard Corp. (fuller's earth and kaolin); General Shale Products Corp. (common clay and shale); Glen Gery Corp. (common clay and shale); Holnam, Inc. (common clay and shale); J.M. Huber Corp. (kaolin) IMERYS (kaolin); Oil-Dri Corp. (fuller's earth); Radex Heraklith Industriesbeteilgungs AG (fire clay and kaolin); and Thiele Kaolin Co. (kaolin).

Most clay mining in the United States was by open pit methods; less than 1% of U.S. clay output was from underground mines. All the underground production was in Ohio, where the clays are mainly underclays associated with coal.

Domestic production data for clays were developed by the USGS from a voluntary survey of U.S. operations. Responses to the survey (354 of 544 sent) account for approximately 85% of the total clay and shale production sold or used listed in table 1. The bulk of the nonrespondents were producers of common clay and shale. Production data for the nonrespondents were estimated from reported prior-year production levels adjusted for trends in the industry and other guidelines.

Ball Clay.—In 2000, 4 companies mined ball clay from 38 quarries in 4 States. Production of domestic ball clay decreased to 1.14 Mt valued at $48.4 million in 2000 from 1.20 Mt valued at $48.0 million in 1999 (table 3). Tennessee supplied 60% of the Nation's output, followed by Texas, Kentucky, and Mississippi. Production increased in Mississippi and decreased in Kentucky, Tennessee, and Texas. Water-slurried ball clay was produced in Kentucky and Tennessee. Airfloat and shredded (unprocessed) ball clay was produced in Kentucky, Mississippi, Tennessee, and Texas.

Hecla Mining Co. sold its subsidiary Kentucky-Tennessee Clay Co. (K-T Clay) to the French investment group IMERYS. K-T Clay is the largest domestic producer of ball clay. The sale consisted of K-T Clay's ball clay operations in Kentucky, Mississippi, and Tennessee and its kaolin operations in Georgia and South Carolina. IMERYS also operates kaolin mines in Georgia (North American Minerals News, 2000b; Hecla Mining Co., 2001).

Unimin Corp. completed its acquisition of United Clays Inc., a division of Watts Blake Bearne & Co. plc (WBB). Unimin also is linked to WBB through its parent corporation SCR Sibelco SA, which has 100% ownership of WBB (North American Minerals News, 2000f).

Bentonite.—In 2000, 20 companies produced bentonite from approximately 82 pits in 11 States. The quantity and value of all varieties of bentonite sold or used decreased to 3.76 Mt valued at $155 million in 2000 from 4.07 Mt valued at $176 million in 1999 (table 5). Production of nonswelling bentonite increased to 400,000 t valued at $14.0 million in 2000 from 392,000 t valued at $13.2 million in 1999. Alabama led all States in the production of nonswelling bentonite, followed by Mississippi, Arizona, Texas, Nevada, California, and Colorado. Production increased in Colorado, Mississippi, and Nevada.

Production of swelling bentonite decreased to 3.36 Mt valued at $141 million in 2000 from 3.68 Mt valued at $163 million in 1999. Wyoming led all States in the production of swelling bentonite, followed by Montana, Utah, California, Texas, Oregon, and Nevada. Production increased in Nevada.

Laporte plc sold its subsidiary Southern Clay Products, Inc. (SCP), to Kohlberg, Kravis, Roberts & Co. LP for $1.18 billion. SCP sold bentonite, hectorite, and organoclay-based products for markets such as oil drilling fluids, cosmetics, and pharmaceuticals (North American Minerals News, 2000d). SCP also commissioned a specialty-products processing unit at its plant in Texas. The unit will produce smectite-based functional additives, including organoclays, nanoclays, and rheological additives (Southern Clay Products, Inc., 2000c). SCP also was awarded damages against Sud-Chemie, Inc., for patent infringement involving two of SCP's organoclay patents (Southern Clay Products, Inc., 2000d).

American Colloid began construction of a blending plant in Butler, GA. This will be the company's 10th blending plant in the United States and the 3d in Georgia. The plant will produce custom bentonite-based binders for foundry metal casting. The company also is diversifying its pet litter lineup through its agreement with The Andersons Inc. to distribute Andersons' corn-cob based litter. American Colloid already markets its clay-based scoopable pet litters (North American Minerals News, 2000a).

Common Clay and Shale.—In 2000, 175 companies produced common clay and shale from approximately 360 pits in 41 States and Puerto Rico. For States not reporting production, common clay and shale probably was mined and sold for construction uses by companies not participating in the USGS canvass of the clay and shale industry. Most companies were manufacturers of structural clay products, such as brick, clay pipe, drain tile, and sewer pipe; lightweight aggregates; and cement. About 89% of the production was used to manufacture brick, lightweight aggregate, and cement.

Domestic sales or use of common clay and shale decreased to 23.7 Mt valued at $135 million in 2000 from 24.8 Mt valued at $155 million in 1999 (table 7). The major producing States, in decreasing order by tonnage, were North Carolina, Texas, Alabama, Georgia, Ohio, Missouri, Virginia, Kentucky, California, and Arkansas.

Fire Clay.—Fire clay producers were mostly refractories manufacturers that used the clays in firebrick and other refractories. In 2000, 42 pits were operated by 12 firms in 6 States.

Fire clay sold or used by domestic producers increased to 476,000 t valued at $7.56 million in 2000 from 402,000 t valued at $6.77 million in 1999 (table 9). Missouri was the leading producing State, followed by Ohio, South Carolina, California, Colorado, and Kentucky. Production increased in California, Colorado, Missouri, and South Carolina.

Fuller's Earth.—In 2000, 17 companies produced fuller's earth (attapulgite and montmorillonite varieties) from 29 pits in 11 States. Production of fuller's earth increased to 2.91 Mt valued at $254 million in 2000 from 2.56 Mt valued at $231 million in 1999 (table 11; discussion under "Prices"). The fuller's earth deposits grade from attapulgite-rich in Florida to montmorillonite-rich further northward into Georgia. Only those clays for which attapulgite is the major clay component are classified as attapulgite. These basically are the gellant-grade fuller's earths in Florida and the southernmost part of

Digitized by Google

Georgia. Going northward into Georgia, the attapulgite content of the fuller's earth declines, and montmorillonite becomes the dominant clay present. This is classified under montmorillonite although it contains minor to trace amounts of attapulgite.

The attapulgite variety of fuller's earth was mined from eight pits in the Florida panhandle and southwestern Georgia. Attapulgite production was estimated to be 292,000 t in 2000, an increase from 289,000 t in 1999. Florida led in the production of attapulgite, followed by Georgia. Production of the montmorillonite variety of fuller's earth was 2.62 Mt in 2000, an increase from 2.28 Mt in 1999. Montmorillonite was produced, in decreasing order by tonnage, in Georgia, Mississippi, Illinois, Missouri, Virginia, California, Florida, Tennessee, Kansas, and Texas.

Sepiolite clay produced in Nevada is included under the attapulgite variety of fuller's earth to protect proprietary information. Production in Kansas is a saprolitic clay but is included under montmorillonite to protect proprietary information.

Kaolin.—In 2000, 22 firms mined kaolin from approximately 93 pits in 10 States. Domestic production decreased to 8.80 Mt valued at $929 million in 2000 from 9.16 Mt valued at $948 million in 1999 (table 13). The leading producing State was Georgia, followed by Alabama, South Carolina, California, Texas, North Carolina, Nevada, Florida, Arkansas, and Tennessee.

Approximately 55% of the kaolin produced was water washed; 16%, airfloat; 14%, calcined; 13%, delaminated; and 2%, unprocessed (table 14). A total of 1.19 Mt valued at $261 million of calcined kaolin was reported. Of this amount, 839,000 t valued at $247 million was pigment-grade (low-temperature). The remainder was refractory-grade (high-temperature) calcined kaolin (table 15). It is believed that refractory-grade calcined kaolin production was greatly underreported by producers in 2000. Actual U.S. production is estimated to be about 1.0 Mt rather than the 354,000 t reported by producers, based on past mining trends and economic conditions.

Kaolin production in Georgia decreased to 7.66 Mt valued at $877 million in 2000 from 8.16 Mt valued at $907 million in 1999. Approximately 62% of the production was sold as water washed; 11%, pigment-grade calcined; 15%, delaminated; 8%, airfloat; and 4%, refractory-grade calcined and unprocessed (table 16). Production of calcined kaolin in Georgia probably was about 1.4 Mt in 2000 rather than 1.07 Mt due to underreporting by refractory producers. Production in South Carolina decreased to 397,000 t valued at $21.9 million in 2000 from 408,000 t valued at $15.7 million in 1999. Approximately 85% of the production was airfloat kaolin, with the remainder being unprocessed (table 18).

Unimin Corp. began negotiations with Süd-Chemie Inc. for the purchase of Albion Kaolin Co. Albion Kaolin was owned by United Catalysts Inc., a subsidiary of Süd-Chemie Inc. Albion Kaolin is the largest producer of airfloat kaolin with plants in McIntrye and Hephzibah, GA. Its main market segment is fiberglass (48% of sales). Other markets were in adhesives, building materials, ceramics, paper, and rubber. Unimin also produces bentonite, feldspar, limestone, mica, nepheline syenite, olivine, quartz (high purity), silica sand, and tripoli (Industrial Minerals, 2000h).

C-E Minerals Inc., part of the French investment group IMERYS, bought North American Processing Co. (NAPCO) from Allied Mineral Products Inc. and Frank & Schulte GmbH. NAPCO has a 70,000-metric-ton-per-year (t/yr) plant in Newell, WV, for processing bauxite, fused alumina, magnesite, magnesia, silicon carbide, and toll processing for other users of refractory materials. C-E Minerals operates facilities in Andersonville, GA, processing kaolin for its alumina silica calcine products (Industrial Minerals, 2000b).

Sparta Kaolin Corp, a subsidiary of Kaoclay Resources Inc., completed its exploration program in east-central Georgia, within 40 kilometers of existing kaolin operations. The company estimates that its deposits contain 43 Mt of kaolin resources. About 35 Mt of this amount has a brightness of 90.9%. The company has about 53 Mt of inferred resources that it is currently investigating. Kaoclay Resources does not intend to enter into the mining industry but is seeking partners to develop the deposit (Industrial Minerals, 2000d).

Thiele Kaolin Co. announced talks with Companhia Vale do Rio Doce (CVRD) in Brazil to be their exclusive marketing agent for paper coating kaolins produced by Para Pigmentos SA (PPSA). PPSA operates a 600,000 t/yr plant in Para, Brazil. It sells its paper coating products mainly to Brazil, Europe, Japan, and other Southeast Asian countries. Thiele Kaolin also is trying to acquire a minority percentage of CVRD's controlling interest in PPSA (North American Minerals News, 2000e).

Consumption

Ball Clay.—The principal domestic ball clay markets, in decreasing order, were floor and wall tile, sanitaryware, and refractories (table 4). Consumption decreased to 1.14 Mt in 2000 from 1.20 Mt in 1999. The largest increase in sales was in miscellaneous ceramics, where sales for electrical porcelain, fiber glass, fine china and dinnerware, and mineral wool increased. Sales for floor tile, refractories, and wall tile applications also increased. Decreases were observed in sales for pottery and sanitaryware. Under miscellaneous sales, sales for waterproofing and sealing applications increased, and sales for brick and drilling mud declined significantly. In general, sales and use of ball clay had increased in recent years because growth in commercial and residential building construction and home renovations has increased demand for sanitaryware, tile, and whiteware. The slight decline in the housing market affected sales in 2000.

Bentonite.—Major markets for bentonite were drilling mud, foundry sand, iron ore pelletizing, and pet waste absorbents. These markets accounted for about 85% of the domestic sales (table 6). Total sales (domestic and exports) of bentonite were approximately 710,000 t for drilling mud (more than 99% was swelling bentonite), 1.07 Mt for foundry sand bond (833,000 t was swelling bentonite), 558,000 t for pelletizing iron ore (all swelling bentonite), 865,000 t for pet waste absorbent (more than 99% was swelling bentonite), and 285,000 t for waterproofing and sealing (more than 99% was swelling bentonite). These five markets accounted for 93% of total bentonite sales.

Data for other bentonite markets were withheld to avoid disclosing company proprietary data. However, more than 90% of the bentonite sold for absorbents, adhesive, animal feed, drilling, pelletizing iron ore, waterproofing, and water treatment and slightly more than 78% of bentonite sold for foundry sand applications was swelling bentonite. Bentonite sold for catalyst; desiccant; filtering, clarifying, and decolorizing of oils and

Digitized by Google

greases; and paint, pharmaceutical, and miscellaneous chemical manufacture applications was largely the nonswelling variety of bentonite.

The major domestic markets for swelling bentonite, in decreasing order, were pet waste absorbents, foundry sand, drilling mud, iron ore pelletizing, and waterproofing and sealing. Major export markets for swelling bentonite were foundry sand, drilling mud, and iron ore pelletizing applications. The major domestic uses for nonswelling bentonite, in decreasing order, were in clarifying, decolorizing, and filtering of oils and greases; foundry sand; catalyst; miscellaneous absorbents; animal feed; and chemical manufacture. Very little nonswelling bentonite was exported.

Common Clay and Shale.—Common clay was used most frequently in the manufacture of heavy clay products, such as building brick, drain tile, flue linings, lightweight aggregate, portland cement, sewer pipe, structural tile, and terra cotta (table 8). Consumption of common clay and shale decreased slightly to 23.7 Mt in 2000 from 24.8 Mt in 1999. The strong housing and commercial building market has helped maintain sales of common clay and shale for brick and lightweight aggregate manufacture for the past several years, but the industry was affected by a slight decline in housing starts in 2000.

Fire Clay.—Fire clay was used in refractory products, such as firebrick and block, grogs and calcines, high-alumina brick and specialties, saggers, refractory mortars and mixes, and ramming and gunning mixes. Fire clays also were used to produce such items as brick and pottery.

Consumption of fire clay increased to 476,000 t in 2000 from 402,000 t in 1999 (table 10). Major markets for fire clay, in decreasing order, were firebrick, refractory mortar and cement, portland cement, miscellaneous refractories, grogs and calcines, quarry tile, pottery, and common brick. Portland cement manufacture accounted for most of the increase in sales under heavy clay products and lightweight aggregates.

Fuller's Earth.—The major domestic uses for attapulgite and montmorillonite varieties of fuller's earth, in decreasing order, were pet waste absorbents; oil and grease absorbents; portland cement manufacture; animal feed; pesticide carrier; filtering, clarifying, and decolorizing of oils and greases; fertilizer carriers; cement manufacture; and pesticide carriers (table 12). Consumption of fuller's earth increased to 2.91 Mt in 2000 from 2.56 Mt in 1999.

Sales of montmorillonite increased to 2.62 Mt in 2000 from 2.28 Mt in 1999. Major domestic markets for montmorillonite, in decreasing order, were pet waste absorbents; oil and grease absorbents; portland cement; animal feed; clarifying, decolorizing, and filtering of oils and greases; and pesticide carrier.

Sales of attapulgite increased to 292,000 t in 2000 from 289,000 t in 1999. Most of the sales data were withheld to avoid disclosing company proprietary data; major markets, in decreasing order, were oil and grease absorbents; drilling mud; fertilizer carriers; paint; pet waste absorbents; adhesives; pesticide carriers; and animal feed.

Sales of montmorillonite variety of fuller's earth accounted for more than 70% of sales of fuller's earth for animal feed; clarifying, decolorizing, and filtering oils and greases; desiccant; oil and grease absorbents; pesticide carriers; and pet waste absorbents. Attapulgite accounted for more than 75% of the sales for adhesive and fertilizer carriers and all of the sales for asphalt tile, drilling mud, gypsum products, paint, pharmaceuticals, roofing granules, and textiles.

Kaolin.—The major domestic markets for kaolin, in decreasing order, were paper coating and filler, refractories (although reported as 425,000 t in 2000 by producers, sales are believed to be closer to 1.0 Mt), paint, fiber glass, rubber, catalyst, and brick (table 20). The largest increase in sales was for paint, which increased by 13% or 38,000 t in 2000. The largest decreases were in paper coating (180,000 t or 6%) and paper fillers (281,000 t or 36%). Both have been affected in recent years by competition from calcium carbonate and a lackluster paper market. Sales of kaolin for refractories were reported to be about 425,000 t in 2000 or about 55% of sales in 1999. Underreporting by refractory producers is believed to have occurred, and refractory sales probably have been about 1.0 Mt for the past 2 years, with 2000 being slightly less than in 1999. This corresponds more closely with recent sales patterns of clay refractories. Major domestic markets for kaolin from Georgia, in decreasing order, were paper coating, paper filling, refractories, paint, and fiberglass (table 17).

The major domestic market for kaolin from South Carolina was rubber, accounting for about 41% of sales. Other major markets, in decreasing order, were catalysts, face and common brick, fiber glass, and roofing granules (table 19).

Absorbent Uses.—Sales for absorbent uses were about 3.07 Mt, an increase of 16% compared with that of 1999. Fuller's earth accounted for 71% of the clay used for absorbents, followed by bentonite. Pet waste absorbents accounted for approximately 90% of absorbent consumption, followed by oil and grease absorbents and miscellaneous absorbent applications.

Ceramics.—All varieties of clays were used in ceramics. Demand for clay in the manufacture of ceramics, ranging from china to sanitaryware to roofing granules, was approximately 2.00 Mt, a slight increase from that of 1999. The largest ceramics market was ceramic floor and wall tile (48%), followed by sanitaryware (18%), catalyst (12%), roofing granules (9%), fine china (3%), and pottery (3%). Ball clay accounted for 38% of the clay used in ceramics, followed by common clay and shale (36%) and kaolin (23%). Small amounts of bentonite, fire clay, and fuller's earth also were used in the manufacture of ceramics. Ball clay dominated the electrical porcelain, glazing, and sanitaryware markets. Common clay and shale was the predominant clay used in roofing granules. Kaolin dominated the catalyst market. Ball clay and common clay and shale were the predominant clays used in floor and wall tile manufacture, and ball clay and kaolin dominated the fine china markets.

Sales of clay tile increased slightly. Apparent consumption of clay floor and wall tile was 212 million square meters valued at $1.95 billion in 2000, an increase from 195 million square meters valued at $1.84 billion in 1999. Domestic manufacturers shipped 60.2 million square meters of clay floor and wall tile valued at $857 million in 2000 compared with 59.1 million square meters valued at $843 million in 1999. Imports were 155 million square meters valued at $1.12 billion in 2000 and 139 million square meters valued at $1.02 billion in 1999 (U.S. Census Bureau, 2001a).

Data on sales of vitreous sanitaryware used in the United States were not available for 2000. In 1999, apparent consumption was valued at $976 million compared with $886 million in 1998. Manufacturer shipments were $932 million in 1999 versus $883 million in 1998. Imports increased to $101

Digitized by Google

million in 1999 from $68 million in 1998 (U.S. Census Bureau, 2000a).

Construction.—Common clay and shale were used to manufacture a wide variety of construction materials, including expanded aggregates, hydraulic cement, and structural clay products.

Expanded Clay and Shale.—Approximately 3.85 Mt of clay and shale was used in the production of lightweight aggregate (table 21). Nearly all the clay used to manufacture lightweight aggregate was common clay and shale. Lightweight aggregates were used in concrete block, structural concrete, and highway surfacing, in decreasing order of consumption.

Hydraulic Cement.—Clays provide the alumina and silica required to manufacture hydraulic cements. In 2000, approximately 4.19 Mt of clays was consumed, a decrease from 5.32 Mt in 1999. In decreasing order, common clay and shale, fire clay, fuller's earth, and kaolin were used in the manufacture of portland cement clinker. More than 92% of the clay consumed by the cement industry was common clay and shale.

Structural Clay Products.—Approximately 14.0 Mt of clays was used in the manufacture of structural clay products, such as building brick, roofing tile, and sewer pipe. Common and face brick accounted for 97% of this total. Other markets, in decreasing order by tonnage, were flue linings, sewer pipe, flower pots, structural tile, terra cotta, drain tile, and roofing. Small amounts of bentonite, fire clay, and kaolin also were used.

In 2000, 8.62 billion building and face bricks valued at $1.69 billion were shipped compared with 8.93 billion bricks valued at $1.63 billion in 1999. Structural facing tile and ceramic glazed brick shipments totaled 28,100 units valued at $13.2 million in 2000 compared with 26,70Q units valued at $14.6 million in 1999. Approximately 47,000 t of structural clay tile valued at $9.07 million was shipped in 2000 compared with 47,200 t valued at $8.49 million in 1999. Shipments of vitrified clay and sewer pipe fittings were 162,000 t valued at $61.7 million compared with 179,000 t valued at $56.6 million in 1999 (U.S. Census Bureau, 2001a).

Drilling Mud.—Sales (domestic and exports) for drilling mud applications were 764,000 t (676,000 t sold domestically and 88,100 t exported). Swelling-type bentonite accounted for approximately 93% of the clay used in drilling mud. Fuller's earth also was used in drilling mud applications.

Drilling activity increased in 2000 with the number of rotary rigs operating as of December 8, 2000, at 1,497 in Canada and the United States compared with 1,210 in 1999 (Oil & Gas Journal, 2000a). The number of exploratory wells drilled was predicted to increase to 2,550 in 2000 compared with 2,138 in 1999 (Oil & Gas Journal, 2000b).

Fillers, Extenders, and Binders.—Clays are used as fillers, extenders, and binders in a wide variety of products, such as adhesives, flooring products, paint, paper, and rubber. About 4.61 Mt of clays was sold for use as fillers, extenders, and binders in 2000 compared with 5.18 Mt in 1999. The bulk of the decline was in sales of kaolin to the paper industry. Paper coating and filling accounted for 72% of domestic sales, followed by paint, 8%; rubber, 5%; and animal feed, 3%. Adhesive; asphalt tile; fertilizer carrier; gypsum products; ink; medical, cosmetic, and pharmaceutical; pesticide carrier; plastic; textile; and wallboard applications each accounted for less than 1.5% of the fillers and extenders markets.

Kaolin accounted for approximately 89% of the clay used in filler and extender applications, followed by fuller's earth, 6%; common clay and shale, 2%; bentonite, 2%; ball clay, 1%; and trace amounts of fire clay. Bentonite was the predominant clay used for ink applications; common clay and shale, in wallboard production; fuller's earth, in fertilizer and pesticide applications; and kaolin, in adhesive, gypsum products, paint, paper, plastics, rubber, and textile markets. Bentonite, fuller's earth, and kaolin were the predominant clays used in asphalt tile, and bentonite and fuller's earth were the predominant clays used in animal feeds and pharmaceuticals.

The U.S. Census Bureau reported shipments of paints and coatings to be 1.48 billion gallons valued at $17.8 billion in 2000 compared with 1.47 billion gallons valued at $17.8 billion in 1999. Architectural paints accounted for 645 million gallons; product coatings, for 453 million gallons; and special purpose coatings, for 181 million gallons compared with 660 million gallons, 440 million gallons, and 174 million gallons, respectively, in 1999 (U.S. Census Bureau, 2001b). Architectural paints are the major market for industrial mineral fillers among the paint types.

Fiberglass.—Domestic sales to the fiberglass industry were 304,000 t in 2000 compared with 329,000 t in 1999. Kaolin was the only clay type used for this application.

Iron Ore Pelletizing.—Sales (domestic and exports) were 558,000 t in 2000 compared with 598,000 t in 1999. Swelling bentonite was the only type of clay used for this application.

Paper Products.—Kaolin accounted for all of the clay sales used for paper coating (2.82 Mt sold domestically and 1.93 Mt exported) and essentially all the clay used for paper filling (506,000 t sold domestically and 100,000 t exported).

Approximately 86.8 Mt of paper and paperboard was produced in 1999. Paperboard accounted for 46.2 Mt of this amount and paper accounted for 40.6 Mt. Paper accounted for 62% of the value of these shipments (McGraw-Hill Companies and International Trade Administration, 2000). In general, slow growth in the paper industry, pressure to reduce paper prices, and increased fuel costs have resulted in reduced returns for the kaolin industry.

Refractories.—Producers reported that 2.15 Mt of clays was used for the domestic manufacture of refractories. As mentioned earlier, it is believed that underreporting occurred in 2000. It is estimated that the reported tonnage should be increased by between 600,000 to 700,000 t, bringing sales for refractory usage to about 2.80 Mt compared with 3.06 Mt in 1999. The largest domestic markets, as reported by producers, were foundry sand (50%), refractory mortar and cement (16%), firebrick (12%), grogs and calcines (10%), alumina specialties (2%), and high alumina brick (1%). The market percentages for refractories must be used with caution for all but the foundry sand and the refractory mortar and cement categories because of the uncertainty in the data for specific market destinations.

Bentonite accounted for 39% of domestic refractory sales, followed by common clay and shale with 22%; kaolin, 20%; fire clay, 16%; ball clay, 3%; and fuller's earth, less than 1%. Fire clay and common clay were the predominate clays used in firebrick; bentonite, in foundry sand; common clay, in refractory mortar and cement; and kaolin, in calcine, grog, high alumina brick, and kiln furniture.

The U.S. Census Bureau reported that shipments of clay refractories were $911 million compared with $971 million in 1998. In 1999, 861,000 t (292 million bricks) valued at $518 million of clay refractory brick and shapes was shipped by

Digitized by Google

manufacturers. This can be subdivided into fire clay brick and shapes, 384,000 t (118 million bricks) valued at $160 million; high alumina brick and shapes, 435,000 t (139 million bricks) valued at $301 million; and insulating brick and shapes, 41,800 t (36.0 million bricks) valued at $56.6 million. Shipments of unshaped clay refractories were 759,000 t valued at $393 million. This can be broken out into refractory mortars, 121,000 t valued at $60.6 million; plastic refractories, 144,000 t valued at $79.1 million; castable refractories, 325,000 t valued at $190 million; and fire clay gunning mixes, 169,000 t valued at $64.2 million. Approximately 150,000 t of miscellaneous refractories valued at $29.40 million and $24.9 million of other unknown types of clay refractories also was sold in 1999 (U.S. Census Bureau, 2000b).

Prices

Ball Clay.—The average value for ball clay reported by domestic producers was $42.46 per metric ton. The average values for imported and exported ball clay were $301.59 and $86.60 per ton, respectively.

Bentonite.—The average value reported by domestic producers for nonswelling bentonite was $35.00 per ton. The average value for swelling bentonite was $41.96 per ton. The average value for all bentonite was $41.22 per ton. The average value of imported bentonite was $345.93 per ton. The average value of exported bentonite was $105.52 per ton.

The price per ton, ex-works, Wyoming, crude, bulk, rail cars, was $23 to $54; foundry grade, bagged, rail cars, $42 to $65 per ton; API-grade, bagged, rail cars, $34 to $44 (Industrial Minerals, 2000f).

Southern Clay Products, Inc., announced average price increases of 6% for its wet-processed organoclay additives and 5% to 7% for its dry-processed organoclay additives (Southern Clay Products, 2000a, b).

Common Clay and Shale.—The average value for all common clay and shale produced in the United States and Puerto Rico was $5.70 per ton. The average value of clay and shale used in lightweight aggregate was $13.40 per ton. The value for lightweight aggregate is an estimate of the clay value. Average prices for lightweight aggregate produced from clay and shale range from $30 per ton to $50 per ton for most applications.

Fire Clay.—The average value for fire clay reported by domestic producers was $15.88 per ton. The average of imported fire clay was $383.56 per ton. The average value of exported fire clay was $86.11 per ton.

Fuller's Earth.—The average value of attapulgite-type fuller's earth was estimated to be $110 per ton. The value reported by producers on the USGS canvass and given in table 11 was believed to be greatly undervalued based on available pricing for attapulgite. The average value of montmorillonite-type fuller's earth was $90.00 per ton. The average value of all fuller's earth was estimated to be $91.83 per ton. The average value of imported fuller's earth was $171.43 per ton. The average value of exported fuller's earth was $183.82 per ton.

The price per ton, ex-plant, Georgia, 40% to 100% less than 325 mesh, truckload, was $181 to $454; granular processed, 40% to 100% less than 4/8 mesh, truckload, $159 to $454; granular, 6/30 mesh, truckload, $109 to $181; and granular, 6/30 mesh, gel grade, bagged, $295 to $635 (Industrial Minerals, 2000f).

Kaolin.—The average value of kaolin was $105.57 per ton for all kaolin grades. The average value for airfloat was $45.99 per ton; refractory grade (high-temperature calcined), $27.57; pigment grade (low-temperature calcined), $294.40; all types of calcined, $219.38 per ton; delaminated, $102.59 per ton; water washed, $100.00 per ton; and unprocessed, $12.57 per ton. The average value of the imported kaolin was $312.00 per ton. The average value of exported kaolin was $168.29 per ton.

The price per ton, ex-works, Georgia, filler, bulk, was $73 to $91; coating, bulk, $76 to $167; sanitaryware-grade, bagged, $53 to $62; tableware-grade, bagged, $114; and calcined, bulk, $305 to $357 (Industrial Minerals, 2000f).

IMERYS announced price increases of 8% for paper-grade kaolin prices. The company also will add energy surcharges of $3.30, $6.60, and $19.80 per ton for its hydrous slurry, hydrous dry, and calcined products, respectively (Chemical Market Reporter, 2000).

Foreign Trade

Ball Clay.—Ball clay exports decreased to 100,000 t valued at $8.66 million, according to the U.S. Census Bureau (table 23). Domestic ball clay producers reported that 164,000 t of ball clay was exported in 2000 (table 4). Some discrepancy may occur if water weight for slurry products is not taken into account. Sales through U.S. mineral brokers, where producers do not know if the ball clay is used domestically or exported, also could explain part of the discrepancy. Imports were 504 t of ball clay valued at $152,000 (table 24).

Bentonite.—Bentonite exports increased to 761,000 t valued at $80.3 million (table 23). Domestic bentonite producers reported exports of 404,000 t (table 6). The discrepancy between producers and the U.S. Census Bureau may result from producers including most of the exports destined for Canadian and Mexican markets (approximately 212,000 t) under domestic sales. Sales through U.S. mineral brokers, where producers do not know if the bentonite is used domestically or exported, also could explain part of the discrepancy.

Bentonite imports consisted mainly of untreated bentonite clay and chemically or artificially activated materials. Imports of untreated bentonite were 8,470 t valued at $2.93 million. Imports of chemically activated material were 17,600 t valued at $8.92 million (table 24).

Fire Clay.—Approximately 216,000 t of fire clay valued at $18.6 million was exported (table 23). In 2000, 73 t of fire clay valued at $28,000 was imported (table 24).

Fuller's Earth.—Approximately 136,000 t of fuller's earth valued at $25.0 million was exported (table 23). Approximately 70 t of decolorizing earth and fuller's earth valued at $12,000 was imported in 2000 (table 24).

Kaolin.—The U.S. Census Bureau reported that 3.69 Mt of kaolin valued at $621 million was exported in 2000 (table 23). Producers reported exports of 2.74 Mt (table 20). Much of the kaolin destined for Canadian paper markets (839,000 t) and some of the 219,000 t of kaolin exports for Mexican markets probably was reported under domestic consumption.

Kaolin imports increased to 62,500 t valued at $19.5 million (table 24). Approximately 75% of the imports was from Brazil, followed by the United Kingdom with 22%.

World Review

World production of bentonite was approximately 9.86 Mt (table 25), fuller's earth production was estimated to be 3.87 Mt

Digitized by Google

(table 26), and kaolin production was 41.2 Mt (common clay and kaolin combined for Colombia, table 27). The United States continued to be the leading producer of all three varieties of clays, followed by Greece and countries of the former Soviet Union for bentonite, Germany for fuller's earth, and Uzbekistan, the United Kingdom, and the Republic of Korea for kaolin. Spain led all countries in the production of sepiolite.

The European Commission set a maximum dioxin concentration of 5 nanograms per kilogram in kaolinitic clay products used for binder, anticaking agents, and coagulants. This standard was established because of the high levels of dioxin in some of the kaolinitic clay from Germany (Industrial Minerals, 2000c).

Brazil.—Rio Capim Caulim SA, partially owned by IMERYS, plans to double its current production capacity of 400,000 t/yr and to introduce new calcined kaolin products for paint applications (Industrial Minerals, 2000a).

Czech Republic.—WBB purchased shares of Kaolin Hlubany, a.s., from Villeroy and Boch AG. Villeroy and Boch owned 94% of Kaolin Hlubany. The company sells about 80,000 t of clay for tableware, sanitaryware, refractory, and tile applications (Ceramic Industry, 2000).

Mexico.—KT Clay completed a $3.5 million expansion of its ball clay slurry plant at Monterrey. The plant, with the most recent expansion, has a capacity exceeding 100,000 t/yr (North American Minerals News, 2000c).

Namibia.—Afhold Ltd. obtained a 15-year license from the Namibian Government to mine sepiolite near Gobabis. The company plans to export the sepiolite to Europe for cat litter applications. The deposit contains 4 Mt of high-grade sepiolite and 5 Mt of lower quality sepiolite. The company will mine the lower quality material first (Mining Journal, 2000).

New Zealand.—IMERYS purchased all shares of New Zealand China Clays Ltd. from Ceramico Corp. Ltd. New Zealand China Clays produced about 15,000 t/yr of halloysite for the tableware market (CI Cybernews, 2000).

Portugal.—WBB created the management group WBB Portugal to handle its clay interests in that country. Portugal has become an important market for exports from the WBB Devon Clays Ltd. operation in the United Kingdom and its joint venture Donbas Clays JSC in Ukraine (Industrial Minerals, 2000i).

Turkmenistan.—Bentonite from the Oglanlinsky clay deposit will be processed at a new bentonite plant in Nebit-Dag, in the Balkansky District. The plant will have a capacity of 50,000 t/yr. The output will be used in ceramic, drilling-mud, and foundry applications (Industrial Minerals, 2000e).

Uzbekistan.—Kaolin, a joint venture between German and Uzbekistani interests, has commissioned a second kaolin processing plant at Angren. The new plant will increase capacity to 200,000 t/yr. The plant processes kaolin primarily for Uzbekistan's ceramic and paper industries, although its kaolin is suitable for pharmaceutical, pigment, and refractory applications (Industrial Minerals, 2000g).

Outlook

The outlook for the clay industry will be mixed for the next few years. Construction-oriented markets are likely to experience very little growth or even slight declines if the U.S. and world economies continue to slow. This will affect sales of clays for adhesives, brick, ceramics, fiber glass, lightweight aggregate, paint, and other construction-oriented markets. Similarly, a slowing economy will affect sales of clays for industrial manufacturing applications, such as foundry sand bond, iron ore pelletizing, and refractories. Interest in oil exploration and processing should provide a slight boost in sales for catalysts and drilling muds. Pet litter markets also should remain strong. Competition in the paper-filler and coating markets and increased fuel costs will continue to hamper the kaolin industry.

TABLE 1
SALIENT U.S. CLAY STATISTICS 1/ 2/

(Thousand metric tons and thousand dollars)

	1996	1997	1998	1999	2000
Domestic clays sold or used by producers:					
Quantity	43,100	42,000	41,900	42,200	40,800
Value	1,710,000	1,670,000	1,670,000	1,570,000	1,520,000
Exports:					
Quantity	4,830	5,080	5,230	4,800	5,260
Value	825,000	860,000	843,000	823,000	896,000
Imports for consumption:					
Quantity	45	64	86	90	96
Value	21,000	23,200	27,700	23,000	34,900

1/ Excludes Puerto Rico.
2/ Data are rounded to no more than three significant digits.

TABLE 2
CLAYS SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 2000, BY STATE 1/ 2/

(Thousand metric tons and thousand dollars)

State	Ball clay	Bentonite	Common clay and shale	Fire clay	Fuller's earth	Kaolin	Total	Total value

TABLE 4--Continued
BALL CLAY SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE 1/

W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes animal feed (1999), asphalt emulsions (1999), rubber (2000), and other fillers, extenders, and binders.
3/ Includes catalysts, electrical porcelain, fiber glass (2000), fin china/dinnerware, glazes, mineral wool, and miscellaneous ceramics.
4/ Includes firebrick, blocks, shapes, high-alumina brick and specialties (1999), and kiln furniture (2000).
5/ Includes brick (common), waterproofing seals, drilling mud (1999), and other unknown uses (1999).
6/ Includes ceramics and glass, fillers, extenders and binders, and floor and wall tile.

TABLE 5
BENTONITE SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY STATE 1/

(Thousand metric tons and thousand dollars)

State	Nonswelling		Swelling		Total	
	Quantity	Value	Quantity	Value	Quantity	Value
1999:						
California	W	W	W	W	23	2,110
Mississippi	W	W	--	--	W	W

TABLE 6--Continued
BENTONITE SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

(Metric tons)

Use	1999	2000
Exports:		
Drilling mud	68,800	56,400
Foundry sand	251,000	233,000
Other 7/	121,000	115,000
Total	440,000	404,000
Grand total	4,070,000	3,760,000

W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes catalysts and pottery.
3/ Includes medical, pharmaceutical, cosmetics, paint, paper filling (2000), pesticides and related products (1999), plastics, asphalt tiles, ink, and miscellaneous fillers and extenders applications.
4/ Excludes shipments to Canada. Total sales in North America were 598,000 metric tons in 1999 and 558,000 metric tons in 2000.
5/ Includes kiln furniture and miscellaneous refractories.
6/ Includes chemical manufacturing, heavy clay products, and other unknown uses.
7/ Includes absorbents, waterproofing and sealing, fillers and extenders, pelletizing, miscellaneous refractories, and other unknown uses.

TABLE 7
COMMON CLAY AND SHALE SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY STATE 1/ 2/

(Thousand metric tons and thousand dollars)

State	1999		2000	
	Quantity	Value	Quantity	Value
Alabama	2,320	23,700	2,090	23,200
Arkansas	1,010	1,510	958	1,170

TABLE 8
COMMON CLAY AND SHALE SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE 1/ 2/

(Metric tons)

Use	1999	2000
Ceramics and glass 3/	181,000	W
Civil engineering and sealing	34,800	28,000
Floor and wall tile:		
Ceramic	400,000	517,000
Other 4/	W	W
Heavy clay products:		
Brick, extruded	12,000,000	11,600,000
Brick, other	1,800,000	1,730,000
Drain tile and sewer pipe	27,000	71,900
Flowerpots	W	W
Flue linings	58,900	259,000
Structural tile	22,700	W
Other 5/	160,000	108,000
Lightweight aggregate:		
Concrete block	2,430,000	2,330,000
Highway surfacing	317,000	239,000
Structural concrete	929,000	941,000
Miscellaneous 6/	259,000	344,000
Portland and other cements	5,010,000	4,030,000
Refractories 7/	785,000	472,000
Miscellaneous 8/	429,000	1,060,000
Total	24,800,000	23,700,000

W Withheld to avoid disclosing company proprietary data; included with "Other" or "Miscellaneous."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Excludes Puerto Rico.
3/ Includes pottery and roofing granules.
4/ Includes quarry tile and miscellaneous floor and wall tiles.
5/ Includes flower pots, roofing tile, terra cotta (2000), and miscellaneous clay products.
6/ Includes miscellaneous lightweight aggregates.
7/ Includes firebrick, block and shapes, mortar and cement, and miscellaneous refractories.
8/ Includes exports, miscellaneous fillers and extenders, asphalt emulsion, asphalt tile (2000), wall board, and other unknown uses.

TABLE 9
FIRE CLAY SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY STATE 1/ 2/

(Thousand metric tons and thousand dollars)

Paint	263,000	290,000
Paper coating	2,990,000	2,810,000
Paper filling	784,000	505,000
Plastic	34,600	49,600
Rubber	85,200	64,400
Other 4/	104,000	100,000
Heavy clay products 5/	W	17,400
Refractories 6/	650,000	278,000
Undistributed 7/	179,000	182,000
Total	5,770,000	4,960,000
Exports:		
Paint	81,500	400,000
Paper coating 8/	1,970,000	1,930,000
Paper filling 8/	110,000	100,000
Rubber	4,670	7,670
Undistributed 9/	234,000	263,000
Total	2,400,000	2,700,000
Grand total	8,160,000	7,660,000

W Withheld to avoid disclosing company proprietary data; included with "Other" or "Undistributed."
1/ Includes airfloat, high- and low-temperature calcined and delaminated, water-washed, and unprocessed kaolin.
2/ Data are rounded to no more than three significant digits; may not add to totals shown.
3/ Includes crockery/earthenware, fine china/dinnerware, pottery, and miscellaneous ceramics.
4/ Includes animal feed; asphalt tile; fertilizers; gypsum products; medical, pharmaceutical, and cosmetics applications; pesticides and related products; textiles; and miscellaneous fillers, extenders, and binders.
5/ Includes brick (common and face), portland cement (1999), and miscellaneous clay products.
6/ Includes firebricks, blocks and shapes, grogs and calcines, high-alumina specialties, kiln furniture (2000), and miscellaneous refractories; also see discussion under "Production: Kaolin."
7/ Includes chemical manufacturing, floor and wall tiles, and other unknown uses.
8/ Some export sales may be included under domestic sales.
9/ Includes adhesives; catalyst (oil-refining); fiberglass; sanitaryware; miscellaneous fillers, extenders, and binders; portland cement; miscellaneous refractories (1999); and other unknown uses (1999).

e/ Estimated. r/ Revised.
1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.
2/ Table includes data available through August 21, 2001.
3/ In addition to the countries listed, Canada and China are believed to produce bentonite, but output is not reported, and available information is inadequate to make reliable estimates of output levels.
4/ Includes bentonitic clays.
5/ Reported figure.
6/ Year beginning March 21 of that stated.
7/ Montmorillite type bleaching clay.
8/ May include other clays.
9/ Dissolved in December 1991; however, information is inadequate to formulate reliable estimates for individual countries, except Armenia, Georgia, Turkmenistan, and Ukraine.

COAL COMBUSTION PRODUCTS

By Rustu S. Kalyoncu

Domestic survey data and tables were prepared by Rustu S. Kalyoncu, physical scientist.

The working definition for solid materials resulting from the combustion of coal has been evolving. Environmental regulators first used the term coal combustion wastes. Later, the term coal combustion byproducts gained popularity. Lately, coal combustion products (CCPs) has become a household term for those in the power industry, the ash marketers, and most users of these materials. The solids included in CCPs are fly ash, bottom ash, boiler slags, and flue gas desulfurization (FGD) material (synthetic gypsum). Fly ash is the fine fraction of the CCPs that is carried out of the boiler by the flue gases. Almost all fly ash is captured by dust collecting systems, such as electrostatic precipitators. Bottom ash is defined as the large ash particles that accumulate at the bottom of the boiler. Boiler slag is the molten inorganic material that is collected at the bottom of the boilers and discharged into a water-filled pit where it is quenched and removed as glassy particles resembling sand.

Electricity accounts for more than one-third of the primary energy used in the United States, and more than one-half of the Nation's electricity is generated by burning coal. Coal burning, combined with pollution control technologies, generates large quantities of CCPs. During 2000, about 860 million metric tons (Mt) of coal was burned, and about 98 Mt of CCPs was generated by the electric utilities.

In addition to the ash, sulfur in flue gases emitted from fossil-fuel-burning electricity-generating plants is also a concern for the environment. The majority of electric power utilities, especially in the Eastern and Midwestern States, use high-sulfur bituminous coal. Increased use of high-sulfur coal has contributed to an acid rain problem in North America. To address this problem, the U.S. Congress passed the Clean Air Act Amendments of 1990 (CAAA '90) (Public Law 101-549) with stringent restrictions on sulfur oxide emissions. The sulfur dioxide (SO_2) reduction provisions of the CAAA, which would be implemented in a two-phase plan to be completed by 2010, forced the electric utilities to find ways of reducing SO_2 emissions. A number of utilities have switched to alternative fuels, such as low-sulfur coal or fuel oil, as partial or temporary solutions to the problem. A significant number of electric utilities still using high-sulfur coal have installed FGD units.

FGD units remove SO_2 from flue gas but, in doing so, generate large quantities of synthetic gypsum (FGD material), which is a mixture of gypsum, calcium sulfite ($CaSO_3$), fly ash, and unreacted lime or limestone. A number of powerplants convert the $CaSO_3$ to calcium sulfate by forced oxidation and take appropriate measures to reduce the other impurities in the FGD material to produce synthetic gypsum that exceeds the specification for wallboard manufacture. Wallboard plants, recently constructed adjacent to such electric utilities, use the FGD gypsum from those electric utilities. The FGD material adds to the accumulation of already high levels of CCPs. About 23 Mt of FGD material was produced in 2000, and about 4.5 Mt (20%) was used mostly for wallboard manufacture.

FGD issues affect, directly or indirectly, coal, gypsum, lime, limestone, and soda ash producers. Increased commercial use of FGD products represents an economic opportunity for high-sulfur coal producers and the sorbent industry (especially lime and limestone). Today, synthetic gypsum competes directly with natural mined gypsum as raw material for wallboard manufacture.

The value of CCPs is well established by research and commercial practice in the United States and abroad. As engineering materials, these products can add value while helping conserve the Nation's natural resources.

Fly ash represents a major component (58%) of CCPs produced, followed by FGD material (24%), bottom ash

Coal Combustion Products in the 20th Century

The history of coal combustion products (CCPs) began 2000 years ago with the use of fly ash by the Romans in the construction of aqueducts and coliseums. The first research on fly ash was reported in the Proceedings of the American Concrete Institute in 1937, which introduced the term "fly ash" to the literature. Chicago Fly Ash Co., formed in 1946, was the first to market fly ash as a construction material for manufacturing concrete pipe. The U.S. Bureau of Reclamation used fly ash on a large scale in the construction of the Hungry Horse Dam in Montana in 1949. Six other dams were constructed during the 1950s using fly ash concrete. Initial markets for fly ash were as a portland cement extender and as an enhancer of the qualities of concrete to meet new postwar requirements.

In 2000, almost 1 billion metric tons of coal was burned, which generated 120 million metric tons of CCPs. Electric utilities alone burned over 860 million tons of coal and generated over 98 million tons of CCPs, almost 30 million tons of which was used in a number of areas, primarily in cement and concrete (11.7 million tons), structural fills (4.9 million tons), waste stabilization (2.0 million tons), road base/subbase (1.2 million tons), and mining (1.1 million tons) applications. Innovative high-volume applications are being developed. In 2000, CCPs were used as a raw material in numerous products ranging from wallboard to bowling balls.

Digitized by Google

(15.5%), and boiler slag (2.5%). Among the major CCP components, fly ash and FGD materials boast the highest use rate at about 32% of the amount produced.

Legislation and Government Programs

The Resource Conservation and Recovery Act (RCRA), enacted in 1976, has been the primary statute governing the management and use of CCPs. CCPs have been the subject of investigation by the U.S. Environmental Protection Agency (EPA), which published its regulatory determination on wastes from the combustion of fossil fuels in May (U.S. Environmental Protection Agency, 2000). The agency concluded that CCPs do not pose sufficient danger to the environment to warrant regulations under section 3001(b)(3)(C) of subtitle C of the RCRA. However, the EPA also determined that national regulations under subtitle D of the RCRA are warranted for CCPs when they are disposed of in landfills or surface impoundments. Furthermore, possible modifications to existing regulations established under the authority of the Surface Mining Control and Reclamation Act are warranted when they are used to fill surface or underground mines. A detailed review of Government regulations was made in an earlier publication (Kalyoncu, 2000).

The EPA, however, remains particularly critical of State programs and is concerned that Federal Government oversight is needed to ensure that mine filling is done appropriately to protect human health and the environment, particularly since mine filling is a recent but rapidly expanding use of coal combustion wastes (U.S. Environmental Protection Agency, 2000, p. 32231).

Production

Table 1 summarizes the historical production and use of CCPs for the years 1996 through 2000. A small, steady increase in CCP production rates through 2000 is apparent. In 1999, it was predicted that fly ash, bottom ash, and boiler slag production could be expected to remain flat in the near future, as no significant increase in the use of coal was planned for electric power generation. An unexpected jump in petroleum prices, however, may well change the Nation's energy equation in favor of increased coal use. An increase in ash generation can be expected with increased coal burning. The commencement of phase two of the CAAA in January 2000 is expected to contribute to a significant increase in synthetic gypsum generation in the years ahead. The energy policies of the new administration, which call for increased use of fossil fuels, especially use of coal in electric power generation, gives an additional reason to anticipate increases in the generation of CCPs.

Tables 2 through 4 list the domestic production and consumption data for 2000. Table 2 lists the total quantities of CCPs (dry and ponded), whereas tables 3 and 4 summarize the dry and ponded CCP data, respectively.

Graphic representations of CCP data are shown in figures 2 through 9. Figures 2 and 3 show historical CCP production and use data, respectively. Total CCPs production and use data for 2000 are presented in figure 4. Figure 5 depicts production by CCP type and region. Figures 6 through 9 show leading uses for fly ash, bottom ash, boiler slag, and FGD material, respectively.

Consumption

The components of CCPs have different uses because they have distinct chemical and physical properties; each one is suitable for a particular application. CCPs are used in cement and concrete, mine backfill, agriculture, blasting grit, and roofing applications. Other current uses include waste stabilization, road base/subbase, and wallboard production (synthetic gypsum). Potential FGD gypsum uses also include applications in subsidence and acid mine drainage control and as fillers and extenders.

Total CCP use in 2000 decreased to 28.59 Mt from 30.00 Mt in 1999, a 4.7% decrease. Fly ash, bottom ash, and boiler slag all showed slight decreases in use, whereas FGD material recorded an 8.7% increase over the 1999 figure (table 1).

Domestic CCP consumption data from 1996 to 2000 are summarized in figure 3. Figures 6 through 9 summarize the use data for individual CCP types. Among the CCPs, fly ash was used in the largest quantities and found the widest range of applications, with about 60% of annual consumption used in various structural applications. Use in cement and concrete production tops the list of leading fly ash applications with more than 50%, followed by structural fills and waste stabilization (figure 6).

Structural fill and road base/subbase applications are major bottom ash uses. About 65% of bottom ash is used in road base/subbase, structural fill, and snow and ice control (figure 7). Minor uses include concrete, mining applications, and cement clinker raw feed.

Bottom ash can also be used as fine aggregate in asphalt paving mixtures. Some bottom ash is sufficiently well graded that pavements containing bottom ash alone can meet gradation requirements. Bottom ash containing pyrites or porous particles is not suitable for use in hot mix asphalt mixtures, where strict gradation requirements exist. It is used more commonly in cold-mix emulsified asphalt mixtures, where gradation requirements and durability are not critical as in hot mix surface mixtures.

Owing to its considerable abrasive properties, boiler slag is used almost exclusively in the manufacture of blasting grit. Use as roofing granules is also a significant market area. Blasting grit and roofing granules make up almost 90% of boiler slag applications (figure 8).

Boiler slag can also be used as fine aggregate, especially in hot mix asphalt owing to its superior hardness, affinity for asphalt, and its dust-free surface, which aids in asphalt adhesion and resistance to stripping. Since boiler slag exhibits a uniform particle size, it is commonly blended with other aggregates for use in asphalt mixtures.

Wallboard manufacture (more than two-thirds of the total), concrete, mining applications, and structural fill account for the bulk of FGD product uses (figure 9). Structural fill and concrete account for a majority of other uses of FGD material. Agricultural uses account for only 2.3% of total FGD material use. However, potential FGD material use in agriculture

Digitized by Google

exceeds even its use in wallboard manufacture. This potential, however, needs to be realized through demonstration studies.

The 1999 annual survey of CCPs elaborated on the unprecedented demand for wallboard experienced across the United States (Kalyoncu, 2001). In an attempt to meet the increased demand, the wallboard industry moved aggressively to increase the manufacturing capacity through new plant construction and succeeded in doing so. With the signs of recent downturn in the economy, however, demand for wallboard will not keep its current levels. U.S. Gypsum Co. closed several plants in Plaster City, PA; Gypsum, OH; and in Plasterco, VA. Georgia Pacific Corp. closed two of its Grand Rapids, MI, wallboard plants. Closures of old and openings of new plants by the industry resulted in net increase in wallboard production capacity, but owing to decline in demand for wallboard, the existing plants were operating below their production capacity (Olson, 2001). The plant closures are not expected to affect synthetic gypsum use by the wallboard industry, because most of the facilities using synthetic gypsum are recently built modern plants. Companies are closing old, antiquated plants that used natural gypsum and are more likely to close similar old plants designed to use natural gypsum as raw material. This will undoubtedly affect the natural gypsum industry.

World Review

Efforts were made to compile world production and consumption data for the year 2000. However, only 1999 data were provided by the respondents. Data were obtained from major European and Asian countries, including India, the Republic of Korea, China, and Russia. Table 5 summarizes partial world CCP statistics. In the table, data from 13 European Union countries are combined under the European Coal Combustion Products Association (ECOBA). ECOBA member countries are Belgium, France, Germany, Greece, Ireland, the Netherlands, Poland, Portugal, Spain, and the United Kingdom. ECOBA members account for over 90% of CCP production in Europe.

In 1999, the ECOBA profitably used 56% (31 Mt) of the 55.5 Mt of CCPs that its member countries generated compared with about 30% use in the United States. Over 18 Mt of the 37 Mt of fly ash produced was used (48% use rate). A slightly smaller fraction (44%) of bottom ash, 100% of boiler slag, and 87% of synthetic gypsum produced found beneficial uses (table 5). Raw material shortages and favorable state regulations account for the higher use rates of CCPs in Europe. As in the United States, ECOBA members used CCPs in a number of applications, with concrete leading the way at 37%, followed by portland cement manufacture with 31% and road construction with 21%; other uses made up the remainder (11%). Among the individual countries contacted, Canada, India, Israel, Japan, and South Africa reported partial CCP production and use data. Canada used about 1.9 Mt (27%) of 7 Mt of CCPs produced, whereas coal-burning electric utilities in India generated about 90 Mt of CCPs in 1999, of which about 13% (11.7 Mt) was used. The remainder was disposed of in wet ponds. In Japan, 1999 figures were 9.1 Mt and 7.65 Mt for production and use, respectively. These figures translate into an 84% use rate for Japan. The high disposal cost of CCPs in Japan ($100.00 per metric ton) make alternative uses economically viable (Mark Early, Barlow Junker Pty Ltd., oral commun., 2001).

Large volume CCP use in India, China, and the Republic of Korea is an environmental and economic necessity owing to the planned increase in coal-fired powerplants to meet future electricity needs and the high ash contents of coal burned. Current burning of coal, containing 40% to 45% mineral matter, generates 90 million metric tons per year (Mt/yr) of CCPs in India, most of which is disposed of in wet ponds in the vicinity of the plants. The situation in the Republic of Korea is even more serious owing to the fact that the Republic of Korea burns more coal for electricity production than any other country in the world. Coal in the Republic of Korea also contains high fractions of mineral matter, which results in the generation of CCP quantities four times that of the United States (table 5) (Ji-Young Ryu, Korea Electric Power Corporation, oral commun., 2001).

Current Research and Technology

Research and development activities have focused on improving FGD processes and finding new applications for CCPs, especially the FGD product. Japanese and West European researchers have led much of the activity in the development of new FGD technologies. Electric utilities in these countries have no room for the disposal of the products from the current FGD processes and are forced to find better solutions to flue gas emission problems. Research efforts emphasize the development of technology that requires less space for installation and yields smaller quantities of products than the well established methods using lime or limestone as sorbents.

Research and development efforts in FGD have been directed, for the most part, toward either decreasing the quantities of the reaction products or increasing their economic value to upgrade them from waste products to resources.

Consol Energy Corp. successfully manufactured aggregates from CCPs using a pelletization process it developed (Aggregates Manager, 2000). Fly ash and synthetic gypsum are combined by disk pelletization with moderate-temperature curing to form aggregates. If commercialized, such manufactured aggregates may eventually play an important role in the 2-billion-ton-per-year aggregates market.

In order to reduce nitrogen oxides emissions to meet the requirements of the CAAA's restrictions on nitrogen oxide (NO_x) emissions, many electric utilities installed no-NO_x burners. No-NO_x burners, however, lead to a significant increase in the unburned carbon content of fly ash, in certain cases exceeding 10%. High carbon content renders fly ash unsuitable for cement and concrete applications, which account for the bulk of fly ash use. Excess unburned carbon in concrete-containing fly ash cement reduces the freeze-thaw resistence of concrete by capturing the air entraining agents that are used to modify the microstructure by introducing controlled porosity.

Researchers at the Pennsylvania State University have developed a method to economically separate unburned coal from fly ash (Skillings Mining Review, 1999). It appears that

Digitized by Google

the unburned carbon separated from the fly ash is suitable for manufacturing activated carbon, which is used in water treatment and gas purification processes. These carbon products have a significant market with 350,000 metric tons per year sold. The unburned carbon, separated from fly ash, does not need cleaning or grinding, nor does it need heating to remove volatiles. While anthracite, which is currently used as the precursor in the manufacture of activated carbon, sells for about $50.00 per metric ton, the unburned-carbon in fly ash can be separated at $10 to $15 per metric ton, and the fly ash can be sold to concrete or cement producers.

Reports of research and development results during the past two decades indicate that an increase in the development of uses for CCPs will happen in small steps. At the 14th International Symposium on Management and Use of Coal Combustion Products, held in San Antonio, TX, in January 2001, researchers from industry, academia, and Federal and State Governments made presentations that covered a range of topics from characterization to applications of CCPs in landfills, agriculture, mine backfilling, acid mine abatement, manufacture of building blocks, and recovery of high-value rare-earth metals. The proceedings of the 14th symposium contain 82 papers, presented in 13 sessions (American Coal Ash Association, 2001).

As construction materials, CCPs add to and enhance the chemical durability while reducing costs. In agricultural applications, gypsum-rich products provide sulfur needed by plants. In waste stabilization, pozzolanic properties of these products can immobilize nuclear and toxic compounds and allow the disposal of such compounds in a safe manner. Substantial benefits to the society will include conservation of land and natural resources and reduction in CO_2 emissions.

There are a number of technical, economic, institutional, and legal barriers to the use of large quantities of CCPs. Technical and economic barriers are not mutually exclusive, in that technological advancements usually result in economic feasibility. Principal technical barriers include issues related to CCP production, specifications and standards, materials characterization, product demonstration and commercialization, and user-related factors.

Economic barriers to increased CCP use can be key among all factors affecting byproduct use. With proper economic incentives other barriers to increased use of CCPs can be overcome. For coal-burning electric utilities, the revenues from the sale of CCPs is often insignificant. The high cost of transporting the low unit-value CCPs and competition from locally available natural materials pose two of the most important economic barriers.

Among the institutional and legal barriers are the lack of knowledge of potential ash uses, the sporadic data on environmental and health effects, the compositional inconsistencies in the products, belief that other raw materials are readily available, the lack of State guidelines, and the viewpoint of the industry that EPA regulations and procurement guidelines are too complicated and rigid rather than being general guidelines for use.

A subcommittee of the American Society for Testing and Materials Committee E-50 on Environmental Assessment, on which the U.S. Geological Survey (USGS) is represented, was recently formed to address the question of standards and definitions of coal and CCP-related terms. The latest draft of the definitions document was evaluated by subcommittee members, and recommendations were submitted to the committee for action in 2001. This draft calls for the change of CCPs to coal combustion byproducts (CCBs), to iterate the ideal definition of a product, which is the principal reason for a process. It is argued that coal is burned to produce energy, not ash. Therefore, energy is the product of coal burning process; anything else is a byproduct.

The perception of potential harm to the environment leads to government policies that translate into rigid barriers to the use of CCPs. The recent decision by the EPA to list CCPs under subsection D of the RCRA, which classifies CCPs as potentially hazardous in mine reclamation and backfill applications, is a formidable barrier to the use of CCPs in mine applications. Researchers and marketing professionals have been making efforts to remove such barriers to the use of these materials.

Concerned industry and government representatives, scientists, and engineers have formed a number of national and international organizations to address the removal of barriers to use of CCPs. Some of the most prominent are the American Coal Ash Association (ACAA), the recently formed Coal Ash Resources Research Consortium (CARRC), the Center for Applied Energy Research , the Coal Combustion Byproducts Recycling Consortium (CBRC), the Coal Combustion Byproduct Information Network Steering Committee (CCBINSC), and a number of State organizations.

The ACAA, founded in 1968 by the coal-burning electric utilities and based in Alexandria, VA, has as its mission the advancement of the management and use of CCPs in ways that are technically sound, economically feasible, and environmentally safe. It serves producers and marketers of CCPs, coal producers, allied trade groups, consultants, and academic institutions. Since its establishment, the ACAA has helped shape the technical, educational, government relations, communications, and marketing efforts funded primarily by membership dues and income from educational programs and sales.

The CARRC, housed at the University of North Dakota Energy and Environmental Research Center, is an international organization of industry and government representatives and scientists working together to advance CCP use. The CARRC works to solve CCP-related problems and promote environmentally safe and technically sound use of CCPs. Over the years, the CARRC has contributed to the generation of scientific and engineering information on CCPs, the development of characterization methods, and demonstration of new CCP uses (University of North Dakota Energy and Environmental Research Center, [undated], What's CARRC?, accessed October 23, 2001, at URL http://www.undeerc.org/carrc/html/Whatscarrc.html).

The CBRC is a program of the National Mine and Land Reclamation Center, located at West Virginia University, in cooperation with the U.S. Department of Energy Technology Laboratory. The objective of the CBRC is to develop technologies for coal-burning utilities to solve problems related to production and use of CCPs. The CBRC has thus far sponsored two major CCP use demonstration projects and has

Digitized by Google

published a request for proposals for a third project (Combustion Byproducts Recycling Consortium, [undated], Home page, accessed October 23, 2001, at URL http://cbrc.nrcce.wvu.edu/cbrchome.htm).

The CCBINSC, established in 1997, is a voluntary planning group made up of representatives from a number of Federal and State Government agencies, including the USGS, and research organizations to compile and disseminate the information available through a comprehensive web site. Since its establishment, the committee organizes and conducts a CCB forum every other year. An extensive source of technical inventories, current research activities, and governmental and legal developments on CCP issues is available on the U.S. Department of the Interior's Office of Surface Mining web site (CCB Information Network, [undated], Steering Committee, accessed October 23, 2001, at URL http://www.mcrcc.osmre.gov/ccb/Steering.htm).

A number of major symposia and conferences are held annually or every other year on the use and management of CCPs. Among such significant periodically held events are the International Ash Utilization Symposium, sponsored and run by the University of Kentucky; the ACAA's International Symposium on Management and Use of CCPs, held on odd-number years; the CCB's forum, sponsored and held by the CCBINSC on even-number years; and the annual International Pittsburgh Coal Conference, organized and run by the University of Pittsburgh.

Outlook

Two principal factors that will affect the size of the coal market and, therefore, quantities of CCPs generated are market deregulation and emissions regulations. Market deregulation will encourage electric utilities to search for the lowest cost fuel, and that will most probably be coal. On the other hand, there is the need to comply with phase two of the CAAA. Phase two of the CAAA, implemented in January 2000, capped powerplant SO_2 emissions nationally at 7.72 Mt/yr. As of January 2000, there were about 10 Mt of SO_2 allowances available for sale to noncompliant plants. The allowances were accrued during phase one of the CAAA. Quick disappearance of these allowances will force utilities to switch to clean fuels or to retrofit powerplants with FGD units.

Increases in the production of fly ash and bottom ash will be proportional to the increase in coal use for electric power production. However, there may be a significant rise in the FGD material owing to the implementation of phase two of the CAAA. Only 10% of the utilities were affected by the first phase of the implementation of the law. A noticeable increase in the quantities of FGD material produced will become apparent in the coming years. Currently, power generation systems with more than 10,000-megawatt (MW) capacity support FGD units, and limestone units with more than 6,000-MW capacity and lime units with nearly 4,000-MW capacity are under construction. Moreover, the construction of limestone systems with 7,000-MW capacity and lime systems with 6,000-MW capacity are in the planning stage. When operational, these systems are expected to more than triple the quantity of FGD material to about 75 Mt/yr from the current level of 24 Mt/yr. With continued installation of FGD units, FGD material production could double the amount of CCPs currently being generated. Combined with the potential effect of future EPA rulemaking, this presents a formidable challenge to electric utilities and CCP-user industries.

To answer the challenge, utilities will continue to look for pollution-prevention technologies that will yield lesser quantities but purer and higher value FGD material. An example of such a trend is seen at Basin Electric Cooperative's Dakota Gasification plant in Beulah, ND, where a wet-ammonia-based FGD unit is used to remove SO_2 in the combustion of otherwise nonsalable fuels derived from gasification of lignite. The resulting ammonium sulfate is sold and used as a sulfur blending stock in fertilizer production (William Ellison, Ellison Consultants, oral commun., 1999).

COBALT

By Kim B. Shedd

Domestic survey data and tables were prepared by Jo-Ann S. Sterling, statistical assistant, and the world production tables were prepared by Linder Roberts and Glenn J. Wallace, international data coordinators.

Cobalt is a strategic and critical metal used in many diverse industrial and military applications. The United States remained the world's largest consumer of cobalt. With the exception of negligible amounts of byproduct cobalt produced as intermediate products from some mining operations, the United States did not mine or refine cobalt in 2000. Since 1993, sales of excess cobalt from the National Defense Stockpile (NDS) have contributed to U.S. and world supplies.

World refined cobalt production increased in 2000. Some of the increase was from new operations in Australia and Uganda and some was from a net increase in production by established producers. During the year, several established producers announced that they would participate in evaluating the potential development of a "second wave" of nickel-cobalt laterite projects in Indonesia and the Philippines.

World demand for cobalt in 2000 was estimated to be similar or slightly less than that of 1999 (Cobalt Development Institute, 2001b). Weekly cobalt prices fluctuated within a narrower range than those during recent years. Annual average prices continued the downward trend that began in 1996.

Salient U.S. and world cobalt statistics for 2000 and the previous 4 years are listed in table 1. With the exception of prices and reported production from foreign countries, all quantity and value data in this report have been rounded to no more than three significant digits. Totals and percentages were calculated from unrounded numbers.

Legislation and Government Programs

The Defense National Stockpile Center (DNSC), U.S. Department of Defense, held nine sealed-bid and three negotiated cobalt offerings during fiscal year 2000 (October 1, 1999, through September 30, 2000). During this period, the DNSC sold 2,720 metric tons (t) of cobalt cathode, granules, and rondelles valued at nearly $78 million (table 2). This represented all of the 2,720-t (6-million-pound) maximum allowed for sale under the fiscal year 2000 Annual Materials Plan (AMP). As of the end of the fiscal year, 1,020 t of cobalt had been sold, but not shipped from the stockpile (U.S. Department of Defense, 2001). The AMP for fiscal year 2001 (October 1, 2000, through September 30, 2001) maintained the maximum allowable sale of cobalt at 2,720 t (Defense National Stockpile Center, 2000).

During 2000, DNSC held nine sealed-bid and three negotiated cobalt offerings and sold 3,080 t of cobalt cathode, granules, and rondelles valued at $89 million. On December 31, the total uncommitted cobalt inventory held by the DNSC was 9,300 t, all of which was authorized for eventual disposal.

Production

With the exception of negligible amounts of byproduct cobalt produced from mining operations in Missouri and Montana, the United States did not mine or refine cobalt in 2000 (Stillwater Mining Co., 2001, p. 9; U.S. Minerals Management Service, 2001, Federal onshore—Collections by commodity/revenue type, CY 2000 Jan-Dec, accessed May 22, 2001, at URL http://www.mrm.mms.gov/Stats/coll.htm).

Formation Capital Corp. of Vancouver, British Columbia, Canada, continued to study the feasibility of developing its 100%-owned Idaho Cobalt Project in the Idaho cobalt belt. The project was to entail underground mining of cobalt-copper-gold ores in Lemhi County, ID, producing concentrates by using mineral flotation, and then refining the cobalt concentrate by

Cobalt in the 20th Century

In 1900, the principal source of cobalt ore was New Caledonia. Although few statistics are available, world cobalt production was probably less than 180 metric tons contained cobalt. This cobalt was used mainly as cobalt oxide in the manufacture of pigments and decolorizers for china, pottery, porcelain, and glass. U.S. apparent consumption was less than 30 tons of cobalt oxide, containing approximately 20 tons of cobalt. Eighty-nine percent of the U.S. supply of cobalt oxide was imported, and 11% was produced domestically from a byproduct of smelting lead ores mined in Missouri.

In 2000, most cobalt was produced as a byproduct of copper or nickel. World production of refined cobalt was 35,200 tons of contained cobalt. The principal sources of cobalt-bearing ores were Australia, Canada, Cuba, the Democratic Republic of the Congo [Congo (Kinshasa)], Morocco, New Caledonia, Russia, and Zambia. Cobalt was used in many diverse commercial, industrial, and military applications. The largest use of cobalt was in superalloys, which were used to make parts for gas turbine engines. Cobalt was also used to make magnets; corrosion- and wear-resistant alloys; high-speed steels; cemented carbides (also called hardmetals) and diamond tools; catalysts for the petroleum and chemical industries; drying agents for paints, varnishes, and inks; ground coats for porcelain enamels; pigments; battery electrodes; steel-belted radial tires; airbags in automobiles; and magnetic recording media. The U.S. apparent consumption of cobalt was 11,700 tons in 2000. With the exception of negligible amounts of byproduct cobalt produced as intermediate products from some mining operations, the United States did not mine or refine cobalt in 2000. U.S. cobalt supply consisted of imports, cobalt-bearing scrap, releases from industry stocks, and sales of excess cobalt metal from the National Defense Stockpile.

Digitized by Google

using a pressure leaching process. In October, Formation Capital entered into an agreement with Sunshine Precious Metals, Inc. to purchase a hydrometallurgical refinery in Big Creek, ID. Formation planned to produce approximately 1,500 metric tons per year (t/yr) of cobalt as oxide, hydroxide, carbonate, and/or cathode, with initial production beginning in late 2003 (Formation Capital Corp., 2001a; b; c, p. 2-3, 8-10). Mining in the Idaho Cobalt Belt dates back to the late 1800s and extended until 1959, when the Blackbird Mine in Cobalt, ID, closed. Noranda Mining Inc. of Salt Lake City, UT, considered reopening the mine in the late 1970s to early 1980s, and Blackbird Metals Inc., a New York-based corporation, planned to buy and reopen the mine in the late 1980s to early 1990s. In both cases, the companies did not pursue their plans and the mine remains inactive.

During the year, U.S. Cobalt Inc. of Denver, CO, worked toward developing the Madison Mine, near Fredericktown, MO. Past production from the mine, which occurred intermittently from the mid-1800s to 1961, yielded cobalt, copper, lead, and nickel. U.S. Cobalt was considering two options for the project—building a fully integrated mine-mill-refinery on the Madison property or sending ores from the mine to be custom milled at a nearby facility, and then shipping the resulting cobalt-nickel concentrate to a smelter or refinery. In October, the company released a new resource estimate for the mine. Using a cobalt equivalent cutoff grade of 0.20%, the measured plus indicated resource was 6.6 million metric tons, grading 0.306% cobalt, 0.743% copper, and 0.470% nickel (U.S. Cobalt Inc., 2001, p. 10-13).

PolyMet Mining Corp. of Golden, CO, continued to study the NorthMet deposit under a lease agreement with USX Corp. of Pittsburgh, PA. NorthMet occurs in the Duluth Complex of northeastern Minnesota, a large layered mafic intrusion that contains, in order of relative abundance, copper, nickel, cobalt, silver, platinum-group metals, and gold. In August, PolyMet released the results from a continuous, fully integrated pilot-plant study of the pressure oxidation leaching process chosen to treat sulfide concentrates from the deposit. Leaching efficiencies for all metals except gold were equal to or greater than those obtained from laboratory scale testing of the process performed in 1999. In December, PolyMet announced that drilling results on the property indicated continuity and consistency in grade between the main ore body and a northeast extension of mineralization. PolyMet planned to complete a prefeasibility study by the end of the first quarter of 2001 (PolyMet Mining Corp., 2000a, b).

U.S. processors made cobalt chemicals and cobalt metal powders from cobalt metal and/or cobalt-bearing scrap. U.S. Geological Survey (USGS) data on chemical and metal powder production, shipments, and stocks were derived from a monthly voluntary survey of U.S. cobalt processors. Information from this survey was used to prepare the statistics on cobalt consumption and stocks in table 3. Five of the seven cobalt processors on this survey provided data. Estimates were made for plants for which data were not provided. Two processors made extra-fine cobalt metal powder in the United States. Carolmet Cobalt Products, a division of Union Minière, Inc., made cobalt metal powder from cobalt metal at its Laurinburg, NC, plant. Osram Sylvania Inc. made cobalt metal powder from scrap in Towanda, PA. Production and shipments of cobalt metal powder are withheld to avoid disclosing company proprietary data.

Consumption

U.S. apparent consumption for 2000, as calculated from net imports, consumption from purchased scrap, and changes in Government and industry stocks, was 9% higher than that calculated for 1999 (see table 1). In 2000, an increase in shipments of cobalt from the NDS was greater than the decreases in net imports and cobalt recovered from scrap.

U.S. reported consumption for 2000 was 3% higher than that for 1999. As compared with that of 1999, metallurgical industries consumed 8% more cobalt and the total reported cobalt consumption in chemical uses was 7% lower. Reported consumption was derived by the USGS from voluntary surveys of U.S. operations. Most of the data on cobalt chemical uses were obtained from the cobalt processors survey. A second survey covered a broad range of metal-consuming companies, such as superalloy, magnetic alloy, and cemented carbide producers. For this survey, nearly 90 cobalt consumers were canvassed on a monthly or annual basis. Reported consumption and stocks data in tables 1 and 3 contain estimates to account for nonrespondents.

Prices

U.S. spot prices for cathode (minimum of 99.8% cobalt), as reported by Platt's Metals Week, fluctuated between $13 per pound and $18 per pound. The lowest prices were reported in February, July, and December, and the highest prices were reported at the end of April-beginning of May and the end of September. Platt's average annual U.S. spot cathode price for 2000 was $15.16 per pound, down by 11% from that of 1999. This price has steadily declined since 1995, when it was $29.21 per pound (table 1).

Trends in Platt's prices for Zambian cobalt (minimum 99.6% cobalt) and Russian cobalt (minimum 99.3% cobalt) were more or less parallel to those for U.S. spot cathode. The annual average of weekly prices for Zambian cobalt was $13.74 per pound, and the annual average of weekly prices for Russian cobalt was $12.98 per pound.

Sales prices for 99.8% cobalt cathode reported by WMC Ltd. at its Internet web site provided some market transparency and became a benchmark for cobalt prices (Metal Bulletin, 2000d; Ryan's Notes, 2000). The trend in these prices was similar to that of Platt's U.S. spot cathode prices. WMC's lowest sales price was $12.40 per pound in late July and its highest sales price was $17.50 per pound in late September.

In October, OM Group Inc. announced that it had established an Internet web site for cobalt sales. OM Group's Internet sales were limited to spot sales of grade B cobalt briquettes, which contained a minimum of 99.8% cobalt. Sale prices during November and December ranged from $12.40 per pound to $13.00 per pound.

Foreign Trade

Net import reliance as a percent of apparent consumption is used to measure the adequacy of current domestic production to meet U.S. demand. Net import reliance was defined as imports minus exports plus adjustments for Government and industry stock changes. Releases from stocks, including shipments from the NDS, were counted as part of import reliance, regardless of whether they were imported or produced in the United States.

Digitized by Google

In 2000, net import reliance as a percent of apparent consumption was 78%. Because there was no measurable U.S. primary cobalt production in 2000, this indicates that 78% of U.S. cobalt supply was from imports and stock releases and 22% was from scrap, which would have been generated domestically or imported.

As shown in tables 4 and 5, in 2000, the United States imported 8% more cobalt than it did in 1999. Eight countries supplied 88% of U.S. imports of unwrought cobalt and cobalt in chemicals. Finland was the leading supplier, followed by Norway, Russia, the Democratic Republic of the Congo [Congo (Kinshasa)], Canada, Belgium, Brazil, and Zambia. Compared with those of 1999, cobalt imports from Belgium, Brazil, Canada, Finland, and Russia increased and imports from Congo (Kinshasa), Norway, and Zambia decreased.

In 2000, the United States imported 214 t, gross weight, of unwrought cobalt alloys valued at $6.4 million. Five countries supplied more than 95% of these materials—Congo (Kinshasa) (45%), Sweden (16%), Belgium (15%), Japan (14%), and the United Kingdom (6%). The United States imported 550 t, gross weight, of cobalt matte, waste, and scrap, valued at $4.1 million. Seven countries supplied more than 90% of these materials—the United Kingdom (43%), France (13%), Germany (11%), Canada (10%), Japan (6%), and Argentina and Belgium (5% each). The United States also imported 359 t, gross weight, of wrought cobalt and cobalt articles valued at $18.8 million. The leading suppliers of these materials were Japan (30%); the United Kingdom (28%); Germany (11%); and Belgium, France, and the Netherlands (5% each).

U.S. exports of unwrought cobalt and cobalt contained in chemicals increased by 70% compared with those of 1999. As listed in table 6, 87% of the cobalt metal and chemical exports was shipped to nine countries—Belgium, Canada, France, Germany, Japan, Mexico, the Netherlands, the Republic of Korea, and the United Kingdom. The remainder was shipped to 41 other countries.

Exports also included 971 t, gross weight, of wrought metal and cobalt articles valued at $37.8 million. Eighty-five percent of these materials was sent to eight countries—Germany (24%), the United Kingdom (23%), Japan (10%), India (9%), Belgium and Canada (6% each), the Republic of Korea (4%), and Netherlands (3%). The remainder was shipped to 35 other countries.

World Review

World refined cobalt production increased in 2000 as compared with that of 1999. Some of the increase in production was from new producers in Australia and Uganda and some was from a net increase in production by established producers. Refinery capacity by country is listed in table 7. Plants that reprocessed refined cobalt, that used secondary materials (scrap) as their main source of feed, or that produced a cobalt product that required further refining were not included.

Australia.—QNI Pty. Ltd. processed lateritic ore imported from Indonesia, New Caledonia, and the Philippines at its Yabulu nickel-cobalt refinery in Townsville, Queensland, and produced 1,520 t of cobalt as cobalt oxide hydroxide, approximately the same amount as the 1,539 t produced in 1999 (Cobalt Development Institute, 2001b). In May, QNI purchased a 40% direct joint-venture interest in the Ravensthorpe nickel project from Comet Resources Ltd. The project involved building a front-end pressure acid leaching plant at Ravensthorpe on the southern coast of Western Australia. Lateritic ore from Ravensthorpe would be processed at the plant to produce an intermediate nickel-cobalt hydroxide, which would then be shipped to Yabulu for refining. During the year, the QNI-Comet joint venture performed laboratory scale and continuous pilot-plant testwork and made revised resource estimates for several of the deposits at Ravensthorpe. The front-end engineering and design phase of the project was expected to be completed during the second quarter of 2001 (Comet Resources Ltd., 2000). QNI planned to expand the Yabulu refinery to accommodate the increase in feed material. Future production from Ravensthorpe was estimated at approximately 35,000 t/yr of nickel and 1,300 t/yr of cobalt. The Yabulu refinery capacity might be increased to 65,000 t/yr of nickel and 3,000 t/yr of cobalt (Billiton plc, 1999).

WMC produced an estimated 800 t of cobalt in intermediate nickel-cobalt mixed sulfide at its Kwinana nickel refinery in Western Australia (WMC Ltd., 1999). The mixed sulfide was refined in Norway by Falconbridge Ltd. under a tolling agreement and the cobalt cathode was offered for sale by WMC on its Internet web site.

Outokumpu Australia Pty. Ltd. produced nickel concentrates from its Black Swan nickel operations in Western Australia. Nickel concentrates from this operation and from WMC's Mount Keith operation, containing an estimated 500 t of cobalt, were exported to Finland for treatment at the Harjavalta refinery (Matheson, 1999).

Anaconda Nickel Ltd. produced 925 t of cobalt as metal powder and briquettes from its Murrin Murrin nickel-cobalt laterite pressure acid leaching operation east of Leonora in Western Australia (Cobalt Development Institute, 2001b). The company cited engineering and materials problems as the causes for delays in commissioning the plant and ramping up production to the stage I design capacity of 45,000 t/yr of nickel and 3,000 t/yr of cobalt. Anaconda hoped to reach stage I capacity by the second half of 2001. During the year, Anaconda worked on a rolling expansion of the Murrin Murrin plant to the stage II capacity of 108,000 t/yr of nickel and 7,600 t/yr of cobalt. The company also studied the feasibility of developing its Mount Margaret project, northwest of Murrin Murrin. Anaconda's long-term (10 year to 15 year) plan was to produce more than 20,000 t/yr of cobalt from three nickel provinces—Murrin Murrin, the Mount Margaret and Murchinson deposits north of Murrin Murrin, and Cawse and Broad Arrow south of Murrin Murrin (Anaconda Nickel Ltd., 2000, 2001; Masterman, 2000; Reuters Ltd., 2000a).

Centaur Mining & Exploration Ltd. produced 998 t of cobalt contained in cobalt sulfide from its Cawse nickel-cobalt laterite pressure acid leaching operation northwest of Kalgoorlie in Western Australia. This represented approximately 67% of the 1,500 t/yr of cobalt design capacity of the refinery. Centaur reported that to reduce operating costs, significant capital expenditure would be required to increase production through debottlenecking and expansion. The company was considering doubling the rate of feed through the autoclave in the refinery. In December, Centaur terminated a preliminary agreement with Anaconda Nickel to study the feasibility of expanding Cawse's refinery capacity and began discussions with other resource corporations regarding various options for the Cawse nickel operations (Centaur Mining & Exploration Ltd., 2000, 2001). Capacity and production of cobalt sulfide from Cawse are not

Digitized by Google

included in tables 7 and 9 because the sulfide is an intermediate product that is upgraded by other cobalt refiners.

Preston Resources Ltd. produced 344 t of cobalt from its Bulong nickel-cobalt laterite pressure acid leaching operation east of Kalgoorlie in Western Australia. Approximately one-half of the cobalt, 170 t, was produced as cobalt cathode, and one-half was produced as an intermediate cobalt sulfide. Production did not reach the forecast levels of 8,100 t/yr of nickel and 700 t/yr of cobalt because of a series of technical problems with the refinery. Preston revised its best-case output to 9,000 t/yr of nickel and approximately 600 t/yr of cobalt. The company intended to work towards stabilizing output rather than expanding capacity as originally planned (Preston Resources Ltd., 2000a, b, 2001; Platts Metals Week, 2001a).

Titan Resources NL, West Perth, Western Australia, worked on developing a metallurgical process that used bacterial oxidation to recover base metals from sulfide ores. In August, Titan announced that it had held discussions with WMC regarding the possible application of the bioleaching process to WMC's currently [2000] subeconomic nickel resources (Titan Resources NL, 2000).

The Doe Run Co. of St. Louis, MO, a major lead producer, provided technical assistance to Compass Resources NL on its Browns lead-copper-cobalt-nickel sulfide project in Northern Territory. The Browns polymetallic deposit could be mined by using a conventional large-scale open pit method. Compass was considering a process that would entail grinding the ore, followed by bulk flotation to produce a mineral concentrate, which would be fed into a furnace where the lead would be fumed off and the cobalt, copper, and nickel would be converted to a sulfide matte. Metals in the matte would be dissolved by using an atmospheric acid leaching process. Copper and cobalt would be removed by using conventional solvent extraction-electrowinning (SX-EW) processes and nickel would be precipitated to a marketable product. Compass estimated an average cobalt production of 2,840 t/yr during the first 10 years of operation (Compass Resources NL, [undated], 2000 annual report—Operations review, accessed April 19, 2001, via URL http://Compassnl.com).

Black Range Minerals Ltd. completed a feasibility study on the Syerston nickel-cobalt-platinum laterite project approximately 400 kilometers northwest of Sydney in New South Wales. The study evaluated ore processing by pressure acid leaching, followed by SX-EW to produce nickel cathode and cobalt cathode. The proposed refinery was to have a design capacity of 20,000 t/yr of nickel and 5,000 t/yr of cobalt. Black Range evaluated several site locations for the refinery—Syerston, Broken Hill in western New South Wales, a site in China, and one in Malaysia—and determined that locating the refinery at one of the offshore sites would have the advantages of more attractive tax regimes and lower energy costs than those in Australia (Black Range Minerals Ltd., 2000, p. 4-5; 2001).

Belgium.—N.V. Union Minière S.A. converted cobalt metal, residues, and other cobalt-bearing materials into cobalt hydroxides, metal powders, oxides, and salts at its facilities in Olen. According to the Cobalt Development Institute (2001b), Union Minière's cobalt production increased by 17% in 2000, to 1,110 t, as compared with the 950 t produced in 1999. During the year, Union Minière began to build a new cobalt oxide plant in Olen to meet an anticipated increase in demand for raw materials for the rechargeable battery market (N.V. Union Minière S.A., 2001, p. 13).

Brazil.—Cia. Niquel Tocantins produced cobalt cathode at its refinery in Sao Miguel Paulista, Sao Paulo State. The refinery used lateritic nickel-cobalt ore from Niquelandia, Goias State, as feed. Production during the past 2 years increased significantly as a result of a 1998 expansion to the refinery that increased the cobalt capacity to 800 t/yr. Niquel Tocantins planned to complete an additional increase in the refinery's capacity in 2002, which would result in an increase in cobalt production to 1,100 t/yr (Metal Bulletin, 2000f, 2001).

Canada.—Falconbridge Ltd. produced 667 t of cobalt in concentrate from its Sudbury, Ontario, mines and 289 t of cobalt in concentrate from its Raglan Mine in Quebec. Nickel-copper matte produced at its Sudbury smelter was refined at the company's Nikkelverk refinery in Norway. In 2000, this matte contained 1,792 t of cobalt; 49% of the cobalt originated from ores produced at company mines, and 51% from custom feed materials, defined as feeds that did not originate from Falconbridge mines. Falconbridge's mine and smelter production were lower than those of 1999 as a result of a strike by production and maintenance workers at the company's Sudbury operations that began on August 1, 2000, and extended until February 20, 2001. During the strike, mining operations at Sudbury were reduced to 20% of normal production rates and smelting operations were reduced to 50% to 60% of prestrike rates (Falconbridge Ltd., 2001a, p. 17, 19).

Inco Ltd. produced cobalt oxide at its Thompson, Manitoba, refinery and cobalt cathode at its Port Colborne, Ontario, refinery from feed materials originating primarily from nickel mines in Thompson and Sudbury, respectively. In 2000, Inco produced 1,470 t of cobalt in Canada from both operations, a 4% increase from the 1,420 t produced in 1999 (Cobalt Development Institute, 2001b).

Inco's development of its Voisey's Bay nickel-copper-cobalt-sulfide deposit in northeastern Labrador continued to be delayed by an impasse between the company and the Province of Newfoundland and Labrador. The Provincial Government refused to give approval for the project without a guarantee that the ores would be refined within the Province, and Inco refused to commit to building the refinery in the Province before it was proven to be technically and economically feasible. During the year, Inco continued with exploration activities at Voisey's Bay to further define the deposit and explore new targets. Inco also continued research and development work on a proprietary hydrometallurgical process for Voisey's Bay sulfide concentrates (Inco Ltd., 2001, p. 18, 43).

The Sherritt International Corp.-General Nickel Co. S.A. joint venture's refinery in Fort Saskatchewan, Alberta, produced a record 2,855 t of cobalt in 2000, a 3% increase from the 2,770 t of cobalt in 1999. The increase in production was attributed to an increase in the cobalt content of feed used by the refinery (Sherritt International Corp., 2001, p. 20). Most of the feed was in the form of nickel-cobalt mixed sulfides from the joint venture's operations at Moa Bay, Cuba. As a result of a U.S. embargo on imports of products originating from Cuba, nickel and cobalt produced by Sherritt cannot be sold to U.S. customers.

Canmine Resources Corp. worked on planning, maintenance, engineering, and basic principal testing of processes for the hydrometallurgical refinery it purchased in late 1999. The North Cobalt, Ontario, refinery was to have an initial output of 300 t/yr of cobalt in carbonate or oxide. Canmine planned to begin production by processing feed materials produced by

Digitized by Google

other companies, including a stockpile of cobalt-silver bearing materials, which Canmine purchased from Agnico-Eagle Mines Ltd. in January 2000. Once details on financing had been finalized, Canmine planned to announce timelines for construction, commissioning, and ramp up of production at the refinery. Future expansions to 1,000 t/yr or 2,000 t/yr of cobalt were being considered, depending in part on the development of Canmine's Werner Lake cobalt project and Maskwa nickel project in southwestern Ontario-southeastern Manitoba (Canmine Resources Corp., 2000, 2001).

China.—An estimated 1,200 t of cobalt metal and chemicals was produced from domestic and imported raw materials (Cobalt Development Institute, 2001b). The largest Chinese cobalt producers were Jinchuan Non-Ferrous Metals Corp. and Ganzhou Cobalt & Tungsten Co., Ltd. Jinchuan produced cobalt cathode and downstream products from domestic nickel-copper-cobalt sulfide ores mined and refined at Jinchuan, Gansu Province. Ganzhou produced cobalt metal powders and salts at Ganzhou, Jiangxi Province. From the 1980s until 1999, this company imported and refined all of the cobalt concentrates produced in Morocco (see "Morocco" section of this report). Cobalt metal powder, oxides, salts, and other products were produced by a number of smaller producers and cobalt processors in China (Cie. de Tifnout Tiranimine, 2001; Song, 2001, p. 3-16).

Congo (Kinshasa).—In March, the Ministry of Mines issued a decree that revoked the contract that established Central Mining Group Corp. S.P.R.L., a joint venture between La Générale des Carrières et des Mines (Gécamines), the Government of Congo (Kinshasa), and Ridgepointe Overseas Developments Ltd. The joint venture had been established in 1998 to manage and rehabilitate the copper-cobalt operations in Gécamines' Central Group. As a result of its revocation, the assets of the joint venture were returned to Gécamines (Metal Bulletin, 2000b).

Gécamines and L'Enterprise Generale Malta Forrest S.P.R.L. produced copper-cobalt concentrates from the Luiswishi Mine, which were purchased by OM Group, Inc. for its Kokkola refinery in Finland under a long-term supply contract. The concentrates produced from Luiswishi were estimated to contain approximately 5,000 t/yr of cobalt (OM Group, Inc., 2001, p. 7).

During the fourth quarter, Gécamines, OM Group, and S.A. Groupe George Forrest completed construction of the Big Hill smelter at Lubumbashi and began producing a cobalt-copper alloy, which was shipped to OM Group's Kokkola refinery. The smelter used slag stockpiled at Lubumbashi as feed. The stockpile was expected to supply the smelter for 20 years at a production rate of 5,000 t/yr of contained cobalt (OM Group, Inc., 2001, p. 3, 7).

Congo Mineral Development Ltd. (CMD), a joint venture between America Mineral Fields Inc. and Anglo American plc, continued to work on the Kolwezi tailings project. During the year, CMD commissioned a pilot plant in Johannesburg, South Africa, to determine a suitable flow sheet for the SX-EW process and began collecting baseline data for the environmental impact study. CMD and Gécamines agreed to implement the project in two phases. In phase one, approximately 3 million metric tons per year (Mt/yr) of tailings would be treated to produce as much as 42,000 t/yr of copper and 7,000 t/yr of cobalt cathode. In phase two, the amount of tailings treated would be doubled. A full feasibility study on the project was to begin after CMD obtained the necessary decrees from the President of Congo (Kinshasa). Upon receipt of these decrees, ownership of the Kolwezi tailings project would be transferred to a new company, KMT Sarl, which would be 60% owned by CMD and 40% owned by Gécamines. CMD had not yet received the decrees by yearend (America Mineral Fields Inc., 2001, p. 2-4, 7).

In late 1999, Melkior Resources Inc. and Gécamines agreed to create La Société Minière de Kabolela et Kipese (SMKK) to mine the Kabolela copper-cobalt and Kipese cobalt-gold-platinum deposits near the city of Likasi. SMKK was 60% owned by Melkior and 40% owned by Gécamines. By the end of 2000, the Kabolela Mine was in production and ore treated at the Kakanda concentrator yielded 27 t of cobalt in concentrates (Melkior Resources Inc., 2000a, b).

The rebellion by military factions dissatisfied with the Government of Congo (Kinshasa) that began in August 1998 continued into early 2001. Political uncertainty resulting from the ongoing civil war delayed the progress of the following joint-venture projects with Gécamines: First Quantum Minerals Ltd.'s copper-cobalt tailings projects at Kolwezi and Likasi; International Panorama Resource Corp.'s Kakanda copper-cobalt tailings project; Iscor Ltd.'s rehabilitation of the Kamoto Mine; and Tenke Mining Corp.'s development of copper-cobalt deposits at Tenke and Fungurume. Also delayed was the Mudima consortium's feasibility study on rehabilitating the mines and plants in Gécamines' Kolwezi Group West (First Quantum Minerals Ltd., 2001, p. 29; Tenke Mining Corp., 2001, p. 16; International Panorama Resource Corp., 2001; Iscor Ltd., [undated], Mining—Base metals—Overview, accessed April 2, 2001, at URL http://www.iscorltd.co.za/mainframe.asp?imgname=01). East Asia Gold Corp. abandoned all rights to claims under agreements with Gécamines to study and develop the Mukondo and Luisha properties (East Asia Gold Corp., 2000).

Côte d'Ivoire.—Falconbridge increased its option to earn interest in the Touba-Biankouma nickel-cobalt laterite project in western Côte d'Ivoire to 85% (Falconbridge Ltd., 2001a, p. 28).

Cuba.—Moa Nickel S.A., which was part of the joint venture between Sherritt and General Nickel, mined nickel-cobalt laterites at Moa Bay and produced mixed sulfides containing 29,520 t of nickel and cobalt, a 9% increase from the 27,020 t produced in 1999. The increase in production was attributed to the systematic upgrading, rehabilitation, and debottlenecking activities that have been undertaken since the inception of the joint venture (Sherritt International Corp., 2001, p. 20). The mixed sulfides produced at Moa were sent to the joint venture's refinery in Fort Saskatchewan, Alberta, Canada. Nickel and cobalt of Cuban origin cannot be imported into the United States because of a U.S. embargo on imports from Cuba.

QNI Pty. Ltd., a subsidiary of Billiton plc, constructed a pilot plant in Perth, Western Australia, to test the pressure acid leaching of nickel-cobalt lateritic ores from its development projects, which included the San Felipe project in the Camaguey Province (Billiton plc, 2000). The San Felipe project was being investigated as a joint venture with Geominera S.A., Cuba's mining investment company.

Finland.—OM Group produced 7,700 t of cobalt in cobalt metal powders, briquettes, oxides, and salts, 24% more than the 6,200 t produced in 1999 (Cobalt Development Institute, 2001b). The Kokkola Chemicals Oy refinery processed cobalt-bearing materials from Australia, Congo (Kinshasa), Russia, the United States, and Zambia (OM Group, Inc., 2001, p. 7). OM

Digitized by Google

Group planned to increase the refinery's capacity to 12,000 t/yr of cobalt (Metal Bulletin, 2000c).

In February, OM Group announced that it had reached an agreement to purchase the Harjavalta nickel refinery from Outokumpu Oyj. Outokumpu's nickel smelter was not included in the sale. Outokumpu planned to continue to smelt nickel concentrates for OM Group until its nickel mines were depleted, at which time Outokumpu would stop producing nickel. OM Group planned to find a new nickel-cobalt feed source for Harjavalta (see "Indonesia" section of this report) and to develop the Harjavalta refinery to be more closely integrated with the Kokkola refinery. Historically most of the nickel and all of the cobalt from Harjavalta have been further processed at Kokkola (OM Group, Inc., 2000b; Outokumpu Oyj, 2000).

France.—The Eramet Group produced cobalt chloride at its refinery at Sandouville, near Le Havre. Feed for the refinery was nickel matte imported from Eramet subsidiary Le Nickel-SLN's Doniambo smelter in New Caledonia.

India.—Three companies refined cobalt from imported raw materials. Nicomet Industries Ltd. produced cobalt cathode and various salts at its plant in Cuncolim, Goa State; Rubamin Ltd. produced cobalt cathode and various salts at its plant in Vadodara, Gujarat State; and Conic Metals Ltd. produced cobalt sulfate and carbonate at its plant in Mumbai, Maharahtra State. In addition to this refinery production, cobalt metal powder was recovered from cemented carbide scrap by Sandvik Asia Ltd. at a pilot plant in Pune, Maharashtra State, and spent catalysts from plants producing terephthalic acid, dimethyl terephthalate, and OXO alcohols were reprocessed by more than a dozen small cobalt chemical processors (Cobalt Development Institute, 2001a).

Indonesia.—State-owned P.T. Aneka Tambang (Antam) exported lateritic nickel-cobalt ore to QNI's Yabulu refinery in Queensland, Australia. Several companies, including QNI, worked on projects to explore and develop Indonesia's nickel-cobalt laterite resources.

In February, OM Group and Weda Bay Minerals Inc. announced that they had signed an agreement to pursue the development of nickel-cobalt laterite deposits on Halmahera Island. Under the agreement, the companies would work together to complete a feasibility study to evaluate the production of an intermediate product containing approximately 30,000 t/yr of nickel and 3,000 t/yr of cobalt. OM Group would purchase all of the production from the first phase of the project as feed for the Harjavalta refinery (see "Finland" section of this report). By midyear, Weda Bay Minerals had started the drilling program and metallurgical test work for the feasibility study (OM Group, Inc., 2000a; Weda Bay Minerals Inc., 2000).

In July, Falconbridge and The Broken Hill Proprietary Co. Ltd. (BHP) announced that they had reached a tentative agreement to form a joint venture to study the feasibility of developing the Gag Island nickel-cobalt laterite project. Several matters had to be resolved before the agreement could be finalized, including clarification of commercial arrangements with Antam, clarification of the forestry classification on Gag Island, and resolution of the scope of work for the feasibility study. During the second half of the year, BHP held discussions with Falconbridge and Antam to resolve these issues (Broken Hill Proprietary Co. Ltd., 2000; BHP Ltd., 2001).

Japan.—Sumitomo Metal Mining Co., Ltd., produced electrolytic cobalt, cobalt oxide, and cobalt salts as a byproduct of nickel at its Niihama nickel refinery in Ehime Prefecture. Although not a large cobalt producing country, Japan was a significant cobalt consumer. The rechargeable battery industry was the largest consumer of cobalt in Japan. Manufacturers of cemented carbides, magnets, specialty steels and other alloys, and video tapes also consumed significant quantities of cobalt (Terada, 2000).

Mexico.—International Curator Resources Ltd. of Vancouver decided not to proceed with its Boleo copper-cobalt project near Santa Rosalia, Baja California. The decision was based on a combination of factors including the company's failure to persuade a partner to invest in the project, continued weak markets for the metals that would have been produced, and technical complexities of the deposit (International Curator Resources Ltd., 2001).

Morocco.—Cie. de Tifnout Tiranimine (CTT) mined cobalt-arsenic deposits at Bou Azzer and produced concentrates, which in past years were all exported to China to be refined. In 1996, Cobalt Metallurgie Bou Azzer (CMBA) built a pretreatment plant at Bou Azzer and a refinery at Guemassa to produce cobalt cathode from tailings generated by past mining operations. In 1999, CMBA installed a second plant at Guemassa and began refining domestic concentrates in addition to tailings. As a result, exports of concentrates to China were expected to decrease and domestic production of refined cobalt was expected to increase. In 2000, CTT and CMBA merged to form one company under the name Cie. de Tifnout Tiranimine. CTT's production of refined cobalt increased by more than 150% to 1,200 t, from the 472 t produced in 1999 (M'Hamdi, 1996; Cobalt Development Institute, 2000; Metal Bulletin, 2000a; Cie. de Tifnout Tiranimine, 2001).

New Caledonia.—Lateritic nickel-cobalt ore was exported to QNI's Yabulu refinery for processing. Nickel matte from Le Nickel-SLN's Doniambo smelter was sent to Eramet's refinery in Sandouville, France, where it was refined into nickel cathode, nickel chloride, and cobalt chloride.

During the year, Inco continued a pilot-plant program to test its proprietary pressure acid leaching-solvent extraction process on nickel-cobalt laterites from the Goro deposit in southern New Caledonia. In December, Inco decided to proceed with the next stage of development of the Goro project. Major activities were to be as follows: to complete a bankable feasibility study; to arrange financing, select an engineering construction consortium, and prepare basic and detailed engineering plans for a commercial-scale refinery; to continue test work at the pilot plant; to complete discussions with the Government of New Caledonia regarding fiscal and regulatory arrangements and secure permits for construction and operation of the refinery; and to bring a partner into the project. Inco was planning to build a refinery with the capacity to produce 54,000 t/yr of nickel and 5,400 t/yr of cobalt. Production was forecast to begin in late 2004 or early 2005. The project was 85% owned by Inco, with the remainder owned by Bureau de Recherches Géologiques et Minières, a French Government agency (Inco Ltd., 2000; 2001, p. 17, 42-43).

Argosy Minerals Inc., in a joint venture with Société des Mines de la Tontouta, studied the feasibility of using pressure acid leaching technology to develop the Nakety nickel-cobalt laterite deposits on the east coast of New Caledonia. During the year, Argosy acquired the rights to develop the nearby Bogota mining concessions and worked towards bringing a major joint-venture partner into the project (Argosy Minerals Inc., 2001, p. 1-9).

Digitized by Google

Norway.—In 2000, Falconbridge produced 3,431 t of cobalt at its Nikkelverk refinery, a 14% decrease from the 4,010 t produced in 1999. The decrease in production was attributed to a shortage of feed materials as a result of the strike by production and maintenance workers at company operations in Sudbury. In September, Falconbridge declared a full force majeure on cobalt shipments to the United States and Europe effective November 1 and on shipments to Japan effective December 1. This was amended to a partial force majeure on shipments to the United States and Europe for December. During 2000, 25% of the cobalt produced at Nikkelverk originated from Falconbridge mines in Canada and 75% originated from custom feeds, defined as feeds that did not originate at Falconbridge mines. The custom feeds included matte from BCL Ltd. in Botswana, scrap, and intermediate materials (Reuters Ltd., 2000b; Falconbridge Ltd., 2001a, p. 18-19; 2001b, p. 15-16).

Papua New Guinea.—During the year, the Ramu nickel-cobalt laterite project received all the permits necessary for its development. On the basis of a feasibility study completed in 1998, the project was to use pressure acid leaching technology to produce 33,000 t/yr of nickel metal and 3,200 t/yr of cobalt as cobalt sulfate. At yearend the project was undergoing a change in ownership structure. Once all transactions were completed, Ramu's ownership was to be as follows: 47.95% Highlands Pacific Ltd., 47.05% Orogen Minerals Ltd., and 5% landowners. The partners planned to bring an additional equity partner into the joint venture (Highlands Pacific Ltd., 2000).

Philippines.—Lateritic nickel-cobalt ore from the Philippines was exported to QNI's Yabulu refinery for processing (Platt's Metals Week, 2000b).

In February, Impala Platinum Holdings Ltd. (Implats) of South Africa announced that it had concluded a memorandum of understanding with Philippine company Philnico Developments Ltd. regarding the Nonoc nickel-cobalt laterite project. Philnico planned to convert the mothballed nickel-cobalt plant at Nonoc in Surigao del Norte, Nonoc Island, from an ammonia leach process to a pressure acid leach process. Under the memorandum of understanding, Implats would fund a bankable feasibility study, and then assuming a positive outcome, invest an additional $75 million and contribute the nickel and cobalt assets of its base metals refinery in Springs, South Africa, to the project, in exchange for a 25% share. Mixed sulfides produced at Nonoc, containing approximately 41,000 t/yr of nickel and 4,000 t/yr of cobalt, would be sent to Springs to be refined. The capacity of the Springs refinery would be increased to handle the additional feed (Impala Platinum Holdings Ltd., 2000).

In April, Sumitomo Metal Mining Co. Ltd. agreed to begin a joint study with Rio Tuba Nickel Mining Corp. The study would examine the feasibility of using pressure acid leaching technology to produce a mixed nickel-cobalt intermediate from low-grade saprolitic and lateritic ores stockpiled at Rio Tuba's nickel mine on Palawan Island. Processing at a rate of 1 Mt/yr of ore was expected to yield 10,000 t/yr of nickel and 550 t/yr of cobalt (Metal Bulletin, 2000e; Reuters Ltd., 2000c).

Crew Development Corp., Vancouver, British Columbia, began a bankable feasibility study on a nickel-cobalt laterite deposit on Mindoro Island. Crew was considering building a refinery that would use pressure acid leaching to produce approximately 40,000 t/yr of nickel briquettes and 3,000 t/yr of cobalt briquettes. The project infrastructure would include an overland pipeline to transport ore slurry from the mine to the refinery, a port, power station, and village to support the operation. Following completion of the study, Crew planned to find a partner to develop the project (Crew Development Corp., 2000b).

Russia.—Nickel and cobalt production in Russia involved a complex flow of ores, flotation concentrates, precipitates, and mattes between various production sites. The main feed materials were domestic nickel-copper sulfide and nickel-cobalt laterite ores and imported nickel- and cobalt-bearing secondary materials. Russia had the capacity to produce refined cobalt at four locations—RAO Norilsk Nickel refineries at Monchegorsk on the Kola Peninsula and Norilsk in Siberia, the Ufaleynickel Joint Stock Co. refinery at Verkhniy Ufaley in the Ural Mountains, and the Yuzhuralnickel Joint Stock Co. refinery at Orsk, also in the Ural Mountains (Roskill Information Services Ltd., 1995, p. 11-15).

Total Russian cobalt production was 22% higher than that of 1999 (Interfax Mining & Metals Report, 2001). Ninety-five percent of this production was by affiliated and dependent companies of RAO Norilsk Nickel. Norilsk Nickel's total production of cobalt in marketable products increased by 6.5% in 2000 compared with that of 1999. As compared with that of 1999, production of cobalt metal increased 24%, production of cobalt sulfate more than tripled, production of cobalt carbonate more than doubled, and production of cobalt oxides decreased (RAO Norilsk Nickel, 2001, p. 3, 20).

During the year, Norilsk Nickel approved a plan to develop the ore reserves and production capacity at the Pechenganickel Territorially Exclusive Structural Subdivision, which was a part of its Kola Mining and Metallurgical Co. subsidiary. Under the plan, production was expected to continue until 2015, which was a reversal of a previous plan to cease mining in that area by 2007 (RAO Norilsk Nickel, 2000).

Ufaleynickel commissioned a direct current arc furnace capable of producing 3,000 to 4,000 t/yr of granulated cobalt. The furnace was intended to replace an existing furnace and enable Ufaleynickel to produce granules in addition to the ingot it had been producing. The furnace's capacity was initially committed to tolling raw materials for Norilsk Nickel (Interfax Mining & Metals Report, 2000a; Metal Bulletin, 2000g).

In return for debt forgiveness, Yuzhuralnickel transferred its pyrometallurgical and hydrometallurgical plants to Yuzhpolimetall, a subsidiary controlled by gas provider Uraltransgaz. This left Yuzhuralnickel with nickel mining at the Buruktalskoye Mine in the Orenburg region and the Sakharinskoye Mine in the Chelyabinsk region and auxiliary and maintenance capacity. Late in the year, Yuzhuralnickel was considering toll-processing cobalt concentrates from Congo (Kinshasa) to improve the profitability of its cobalt production (Interfax Mining & Metals Report, 2000b, c, d).

South Africa.—Cobalt was mined as a byproduct from six platinum-group metal mines and as a coproduct from one nickel mine (Ngcai, 2001). Two South African companies produced refined cobalt as a byproduct of domestic platinum mining and refining. Rustenburg Base Metal Refiners Pty. Ltd. produced cobalt sulfate at its refinery near Rustenburg, Northwest Province. Impala Platinum Ltd. produced cobalt metal powder at its base metals refinery near Springs, Gauteng Province. Impala was considering expanding the capacity of the Springs refinery to 60,000 t/yr of nickel and 4,200 t/yr of cobalt to accommodate an increase in feed that would result from the

Digitized by Google

development of the Nonoc project in the Philippines (see "Philippines" section of this report).

During the fiscal year ending June 30, 2000, the Nkomati joint venture between Anglovaal Mining Ltd. (Avmin) and Anglo American produced 227 t of cobalt in concentrates from the Nkomati nickel sulfide mine in Mpumalanga Province. During the previous fiscal year, 211 t of cobalt in concentrates was produced. Avmin was considering expanding production from the mine (Anglovaal Mining Ltd., 2000).

Union Mineral Concentrators Pty., a Union Minière subsidiary, produced cobalt compounds from low-grade cobalt-containing residues in Roodepoort, near Johannesburg. During the year, Union Minière expanded the plant's capacity and broadened the range of compounds produced (N.V. Union Minière S.A., 2001, p. 14).

International Metal Processing (Pty.) Ltd. worked on a 3-year redevelopment and extension program to enhance its cobalt-copper-nickel refinery in Brakpan, Gauteng Provence. At the refinery, mineral concentrates were processed to produce cobalt cathode, metal powder, oxides and salts {International Metal Processing (Pty.) Ltd., [2000], Products produced, accessed May 8, 2001, at URL http://www.intmetals.com/Products.htm}.

Uganda.—Banff Resources Ltd., of Vancouver continued to focus its efforts on commissioning the Kasese cobalt refinery in southwestern Uganda. The refinery was designed to recover cobalt from stockpiled pyrite concentrates by using bacterial leaching followed by SX-EW. During the year, Banff made changes to the plant configuration to improve throughput, oxygen dispersal, and bacterial activity levels. By yearend, 420 t of cobalt cathode had been produced at Kasese, but throughput and production rates remained significantly below the engineered design capacity of 1,000 t/yr of cobalt (Banff Resources Ltd., 2001; Cobalt Development Institute, 2001b).

Zambia.—In March, the Government of the Republic of Zambia completed the privatization of Zambia Consolidated Copper Mines Ltd. (ZCCM) with the sale of ZCCM's remaining assets. Mopani Copper Mines plc, which was owned by the consortium of First Quantum and Glencore International AG (90%) and ZCCM (10%), acquired ZCCM's Mufulira division and certain assets of the Nkana division. The Mufulira division consisted of a copper mine, concentrator, smelter, and refinery. The Nkana assets included in the sale were the mine, concentrator, and cobalt plant, but not the smelter, copper refinery, and acid plant. Following acquisition, Mopani focused its efforts on restructuring, hiring, and training personnel and management, recapitalizing the operations, renegotiating supply contracts, purchasing spares and consumables, rehabilitating the plants and equipment, and underground mine development. Cobalt production from the Nkana cobalt plant was estimated to be 1,026 tons in 2000. The plant processed concentrates from Mopani's Nkana concentrator, the Chibuluma Mine, and on a tolling basis, Konkola Copper Mines plc operations (First Quantum Minerals Ltd., 2000; 2001, p. 15, 23; Cobalt Development Institute, 2001b).

Konkola Copper Mines, which was 65% owned by Zambia Copper Investments Ltd., a subsidiary of Anglo American, 20% by ZCCM, and 7.5% each by CDC Financial Services (Mauritius) Ltd. and the International Finance Corp., acquired the assets of ZCCM's Konkola division, including the Konkola Deep mining project; Nchanga division, with its Chingola refractory ore stockpiles; and Nampundwe pyrite mine. Following acquisition, Konkola Copper Mines began refurbishing the assets, revalidating the feasibility study on the Konkola Deep mining project, and seeking long-term financing for the project (Zambia Copper Investments Ltd., 2001). Konkola Copper Mines was also granted a 5-year option to acquire ZCCM's Nkana smelter, copper refinery, and acid plant. These assets were transferred to ZCCM (SmelterCo) Ltd., a wholly owned subsidiary of ZCCM, and were to be managed by Anglo American during the option period (Anglo American plc, 2000).

Chambishi Metals plc toll-refined copper-cobalt concentrates from mining operations in Zambia and heterogenite from Congo (Kinshasa) and produced 2,316 t of cobalt metal at its Chambishi cobalt plant. Production was impacted by lower than anticipated quantities and grades of feed materials. During the year, Chambishi worked on building a new smelter and matte leach facility at the plant. The new facility was designed to produce cobalt and copper from slag stockpiled at Nkana. Production from the new facility was expected to be 4,000 t/yr of cobalt and approximately 3,500 t/yr of copper. This would be in addition to the cobalt and copper produced by toll treating concentrates. At yearend, construction of the new facility was nearly completed and commissioning had begun. Production of the first salable metal from slag was planned for March 2001 (Anglovaal Mining Ltd., 2000, 2001; Cobalt Development Institute, 2001b).

Copper and cobalt production from Roan Antelope Mining Corp.'s Baluba and Luanshya mines decreased significantly from that of 1999 owing to financial problems that resulted in the Copperbelt Energy Corp. cutting the operation's power supply on several occasions. In late November, Roan Antelope was put under receivership because of unpaid debts. In early 2001, it was announced that the company's assets, including the Baluba and Luanshya mines, the Muliashi deposit, and approximately 10 Mt of smelter slag, would be put up for sale (Reuters Ltd., 2000d; Platts Metals Week, 2001b).

Approximately 100 t of cobalt was produced from the Chibuluma West Mine. The mine is 85% owned by Metorex Ltd., a subsidiary of Crew Development Corp., and 15% owned by ZCCM (Crew Development Corp., 2000a).

In late 1999, Orion Mining and Exploration Ltd. purchased and began rehabilitating the cobalt processing plant at Kabwe, which had been idle since 1998, when Colossal Resources Corp. ceased processing slag from the former ZCCM Nkana division. In 2000, Orion started processing slag imported from Congo (Kinshasa) and exporting the resulting cobalt alloy to China and Europe (Platt's Metals Week, 2000a, c).

Outlook

World cobalt production is expected to continue to increase. Production from new plants in Australia, Congo (Kinshasa), and Uganda is expected to ramp up during the next few years and output from some established refineries is likely to increase from 2000 levels. In addition, there are numerous projects in the prefeasibility, feasibility, or development stage in Africa, the Asia/Pacific region, and North America that include cobalt production. In nearly all of the proposed projects in the Asia/Pacific region, cobalt would be produced as a byproduct of nickel. Progress on these projects will depend more on the nickel market than on the cobalt market.

Another component of world supply is U.S. Government sales of cobalt from the NDS. Offers of NDS cobalt are

Digitized by Google

expected to continue at the rate set each year under the AMP until the amount authorized for disposal has been sold. If the current (fiscal year 2001) AMP level of 2,720 t (6 million pounds) was maintained, and the amount of cobalt sold each year was close to the AMP level, then the NDS cobalt sales program could extend into 2004. However, the National Defense Authorization Act for Fiscal Year 1998 gave specific guidelines for cobalt disposals during fiscal years 2003 through 2007. During this 5-year period, cobalt disposals were required to result in receipts equal to the following amounts: $20 million during fiscal year 2003, $50 million during fiscal year 2004, $64 million during fiscal year 2005, $76 million during fiscal year 2006, and $34 million during fiscal year 2007. As part of the Act, the DNSC was not permitted to dispose of more than 6,350 t (14 million pounds) of cobalt during the 5-year period, and each year the DNSC would not be permitted to dispose of more cobalt than necessary to meet the specified dollar amount (U.S. Department of Defense, 2001, p. 37). Future cobalt prices and efforts by DNSC to meet, but not exceed, specific dollar amounts could impact the amount of cobalt available for sale each year.

Future demand will dictate how much additional cobalt the market can bear. Superalloys, which are used to make turbine parts for jet engines and land-based electrical power generators, continue to be the largest market for cobalt. Demand for jet aircraft and smaller power stations has been strong and is expected to trend upwards. The rechargeable battery industry has been rapidly increasing the amounts of cobalt it uses in recent years. Future growth in cobalt demand by this industry will depend on a combination of factors including the overall demand for batteries, the types of batteries produced, the availability and price of cobalt, and cobalt's image in terms of its toxicity, recyclability, security of supply, and stability of its price (Burstow, 2000; Gellens, 2000; Cundy, 2001; Falconbridge Ltd., 2001a, p. 32; Southwood and Gray, 2001).

Cobalt supply and demand are believed to be roughly in balance and are expected to remain in balance until 2004 or 2005 (Searle, 2001). The general consensus, however, is that the future increase in cobalt supply will be at a greater rate than the increase in demand, and that a resulting surplus will put downward pressure on cobalt prices. Several analysts have forecast that prices will drop to the $6 to $10 per pound range in 2 to 5 years (Burstow, 2000; Bacon and others, 2001, p. 9; Searle, 2001; Southwood and Gray, 2001).

TABLE 1
SALIENT COBALT STATISTICS 1/

(Metric tons, cobalt content, unless otherwise specified)

	1996	1997	1998	1999	2000
United States:					
Consumption:					
Reported	7,990	8,910	9,130	8,410 r/	8,700
Apparent	9,380	11,200	11,500	10,700	11,700
Imports for consumption	6,710	8,430	7,670	8,150	8,770
Exports	1,660	1,570	1,680	1,550	2,630
Stocks, December 31:					
Industry 2/	794	763	751 r/	738 r/	780
U.S. Government 3/	18,700	17,100	14,700	13,200	10,200
Price, metal, per pound 4/	$25.50	$23.34	$21.43	$17.02	$15.16
World, production:					
Mine	26,200	27,200 r/	34,400 r/	30,600 r/	33,300 e/
Refinery	25,600	27,100 r/	30,900 r/	32,400 r/	35,200

e/ Estimated. r/ Revised.
1/ Data are rounded to no more than three significant digits, except prices.
2/ Stocks held by cobalt processors and consumers.
3/ Defense National Stockpile Center. Includes material committed for sale pending shipment.
4/ Annual average U.S. spot price for minimum 99.8% cobalt cathode reported by Platt's Metals Week.

TABLE 2
U.S. GOVERNMENT NATIONAL DEFENSE STOCKPILE SALES AND SHIPMENTS 1/

(Metric tons, cobalt content)

	1999	2000
Sales:		
Fiscal year 2/	1,960	2,720
Calendar year	2,230	3,080
Shipments: 3/		
Fiscal year 2/	1,670	2,150
Calendar year	1,530	2,960

1/ Data are rounded to no more than three significant digits.
2/ Twelve-month period ending September 30 of year stated.
3/ Calculated from year end inventory levels.

Source: Defense National Stockpile Center.

TABLE 3
U.S. REPORTED CONSUMPTION AND STOCKS OF COBALT 1/ 2/

(Metric tons, cobalt content)

	1999	2000
Consumption by end use:		
Steels	154	163 3/
Superalloys	3,830	3,800 3/
Alloys (excludes steels and superalloys):		
Magnetic alloys	794	544 3/
Other alloys 4/	291	1,020 3/
Cemented carbides 5/	755	760

See footnotes at end of table.

TABLE 3--Continued
U.S. REPORTED CONSUMPTION AND STOCKS OF COBALT 1/ 2/

(Metric tons, cobalt content)

	1999	2000
Consumption by end use--Continued:		
Chemical and ceramic uses	2,530	2,360
Miscellaneous and unspecified	63 r/	63
Total	8,410 r/	8,700
Consumption by form:		
Chemical compounds (organic and inorganic) 6/	1,910	1,840
Metal	3,780	4,320
Purchased scrap	2,720	2,550
Total	8,410 r/	8,700
Stocks, December 31: 7/		
Chemical compounds (organic and inorganic) 6/	251	252
Metal	322	370
Purchased scrap	165	159
Total	738 r/	780

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes estimates.
3/ Data not comparable with those for 1999 because of a change in reporting.
4/ Includes nonferrous alloys, welding materials, and wear-resistant alloys.
5/ Includes diamond tool matrices, cemented and sintered carbides, and cast carbide dies or parts.
6/ Includes oxides.
7/ Stocks held by cobalt processors and consumers.

TABLE 4
U.S. IMPORTS FOR CONSUMPTION OF COBALT, BY FORM 1/

(Metric tons unless otherwise specified)

		1999	2000
Metal: 2/			
Gross weight		6,800	7,210
Cobalt content 3/		6,800	7,210
Value	thousands	$229,000	$213,000
Oxides and hydroxides:			
Gross weight		1,260	1,540
Cobalt content 3/		910	1,110
Value	thousands	$33,700	$37,100
Other forms:			
Acetates:			
Gross weight		158	183
Cobalt content 3/		38	44
Value	thousands	$1,270	$1,290
Carbonates:			
Gross weight		58	5
Cobalt content 3/		27	2
Value	thousands	$548	$103
Chlorides:			
Gross weight		35	33
Cobalt content 3/		9	8
Value	thousands	$702	$295
Sulfates:			
Gross weight		1,360	1,490
Cobalt content 3/		366	402
Value	thousands	$9,840	$9,340
Total:			
Gross weight		9,670	10,500
Cobalt content 3/		8,150	8,770
Value	thousands	$275,000	$261,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Unwrought cobalt, excluding alloys and waste and scrap.
3/ Estimated from gross weights.

Total	26,200	27,200 r/	34,400 r/	30,600 r/	33,300

e/ Estimated. r/ Revised.

1/ World totals and estimated data are rounded to three significant digits; may not add to totals shown.

2/ Table includes data available through June 18, 2001. Figures represent recoverable cobalt content of ores, concentrates, or intermediate products from copper, nickel, platinum, or zinc operations. Morocco was the only country where cobalt was mined as a primary product.

3/ In addition to the countries listed, Bulgaria, Indonesia, the Philippines, and Poland are known to produce ores that contain cobalt, but information is inadequate for reliable estimates of output levels. Other copper-, nickel-, platinum-, or zinc-producing nations may also produce ores containing cobalt as a byproduct component, but recovery is small or nil.

4/ Quantities of cobalt contained in intermediate or refined metallurgical products produced from Australian and imported ores. Cobalt content o latertic nickel ore, nickel concentrate, and zinc concentrate originating in Australia was estimated as follows, metric tons: 1996--1,400; 1997--1,600; 1998--4,000; 1999--7,000; and 2000--5,100.

5/ Reported cobalt content of pelletized nickel-copper matte.

6/ Reported figure.

7/ Assay content of cobalt in concentrates produced. The cobalt content of all products derived from ores of Canadian origins, including cobalt oxide shipped to the United Kingdom for further processing and nickel-copper matte shipped to Norway for refining, was reported as follows, in metric tons: 1996--2,150; 1997--2,168; 1998--2,262; 1999--2,014 (revised); and 2000--2,013.

8/ Cobalt content of concentrates and tailings.

9/ Determined from reported nickel-cobalt content of sulfide production.

10/ Estimated cobalt content of only those ores from which it is assumed cobalt is recovered. Cobalt content of total ores mined is assumed to be as follows, in metric tons: 1996-2000--1,400.

11/ Cobalt content of concentrates.

12/ Quantities of cobalt contained in intermediate or refined metallurgical products (cobalt chloride, cobalt oxide hydroxide, and cobalt sulfide) produced from New Caledonian ores exported to Australia and France. Cobalt content of total ores mined is estimated as follows, in metric tons: 1996--12,200; 1997--13,600; 1998--12,500 (revised); 1999--11,000 (revised); and 2000--12,000.

13/ Data for 1996 through 1998 are for the fiscal years beginning April 1; data for 1999 through 2000 are for the calendar years.

14/ Cobalt content of intermediate products produced in Zimbabwe from ores originating in Botswana and Zimbabwe.

COLUMBIUM (NIOBIUM) AND TANTALUM

By Larry D. Cunningham

Domestic survey data and tables were prepared by Robin C. Kaiser, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Columbium [Niobium (Nb)] is vital as an alloying element in steels and in superalloys for aircraft turbine engines and is in greatest demand in industrialized countries. It is critical to the United States because of its defense-related uses in the aerospace, energy, and transportation industries. Substitutes are available for some columbium applications, but, in most cases, they are less desirable.

Tantalum (Ta) is a refractory metal that is ductile, easily fabricated, highly resistant to corrosion by acids, a good conductor of heat and electricity, and has a high melting point. It is critical to the United States because of its defense-related applications in aircraft, missiles, and radio communications. Substitution for tantalum is made at either a performance or economic penalty in most applications. Neither columbium nor tantalum was mined domestically because U.S. resources are of low grade. Some resources are mineralogically complex, and most are not currently (2000) recoverable. The last significant mining of columbium and tantalum in the United States was during the Korean Conflict, when increased military demand resulted in columbium and tantalum ore shortages.

Pyrochlore was the principal columbium mineral mined worldwide. Brazil and Canada, which were the dominant pyrochlore producers, accounted for most of total estimated columbium mine production in 2000. The two countries, however, no longer export pyrochlore—only columbium in upgraded valued-added forms produced from pyrochlore.

Columbium (Niobium) and Tantalum in the 20th Century

Columbium.—Columbium (niobium) was discovered in 1801; prior to 1918, however, most U.S. interest in columbium was for experimental purposes. Commercial columbium usage began around 1925 when it was added to tool steel as a substitute for tungsten. In 1933, columbium (in the form of ferrocolumbium) was first used in stainless steel, and about 1935, columbium was added to superalloys for use in gas turbines. About 3.5 metric tons of columbium-bearing minerals valued at about $4,520 was reported shipped from domestic mines in 1935. Imports of columbium-bearing minerals were about 540 tons valued at about $107,000, with Nigeria accounting for most of the imports. Nigeria was the leading source for columbium-bearing minerals, and the country shipped its entire output to the United States.

In 2000, there was no domestic columbium mining, and the United States satisfied its columbium requirements primarily by importing ferrocolumbium and columbium oxide from Brazil, ferrocolumbium from Canada, and columbium-bearing mineral concentrates for processing mainly from Australia and Nigeria. U.S. columbium imports totaled about 6,500 tons of contained columbium valued at about $110 million. Brazil and Canada were the world's largest producers of columbium minerals, together accounting for more than 95% of the total. Ferrocolumbium and columbium metal, alloys, and compounds were produced in the United States by six companies located mostly in the eastern United States. Columbium consumption in the United States was mainly as ferrocolumbium by the steel industry and as high-purity columbium alloys and metal by the aerospace industry. Steelmaking accounted for more than 75% of reported columbium consumption, with the value of consumption estimated to be about $70 million.

Tantalum.—Tantalum was discovered in 1802. Commercial use of tantalum began in Germany in 1903 with the production of tantalum wire to replace carbon in incandescent light filaments. By 1909, tungsten began to replace tantalum in filaments, and by 1912, the substitution was complete. During this period, U.S. tantalum requirements were imported from Germany. By 1918, U.S. demand for tantalum for experimental purposes was large enough that about 2 metric tons of tantalum-bearing minerals valued at about $2,250 was marketed from material mined in South Dakota. Tantalum carbide was produced in the United States in 1929, and the tantalum capacitor was developed in 1940. There was no reported domestic tantalum mine production in 1940, and U.S. imports of tantalum minerals totaled about 222 tons valued at about $260,000. Australia was thought to be the major producer of tantalum minerals at that time.

In 2000, there was no domestic tantalum mining, and the United States satisfied its tantalum requirements by importing alloys, metal, and powder from China, Japan, and Thailand, and tantalum-bearing mineral concentrates for processing mainly from Australia, Canada, and Nigeria. U.S. tantalum imports totaled more than 900 tons of contained tantalum valued at more than $190 million. Australia was the world's largest producer of tantalum mineral concentrates and accounted for more than 60% of U.S. imports. Tantalum metal, alloys, and powders were produced in the United States by three companies located in the eastern part of the United States. The major use (more than 60%) for tantalum as tantalum metal powder was in the production of electronic components, mainly tantalum capacitors. Tantalum was also consumed in cemented carbides and in superalloys. The value of tantalum consumed in the United States in 2000 was estimated to be about $200 million.

Digitized by Google

Brazil exported mostly regular-grade ferrocolumbium and columbium oxide, and Canada exported regular-grade ferrocolumbium. The remaining columbium mineral supply came from the mining of columbite in Nigeria and tantalite-columbite, mostly in Australia, Brazil, and certain African countries. Tantalum mineral was produced mostly from tantalite-columbite mining operations in Australia, which was almost 60% of total estimated tantalum mine production in 2000, and from other tantalum mine operations in Brazil, Burundi, Canada, Congo (Kinshasa), Ethiopia, Nigeria, and Rwanda. The reliance on tantalum-containing tin slags as a source of tantalum supply remained low.

The United States remained dependent on imports of columbium and tantalum materials; Brazil was the major source for columbium, and Australia, the major source for tantalum. The Defense National Stockpile Center (DNSC) offered and sold selected columbium and tantalum materials from the National Defense Stockpile (NDS). The Generalized System of Preferences (GSP), a renewable preferential trade program, was extended to September 30, 2001. Columbium price quotations remained stable. Tantalum price quotations for tantalite ore escalated amidst concerns about the status of the world tantalum supply. Overall reported consumption of columbium in the form of ferrocolumbium and nickel columbium increased, with demand for columbium in superalloys up significantly. Tantalum consumption increased.

Legislation and Government Programs

Summaries of important columbium and tantalum statistics are listed in tables 1 and 2, respectively. To ensure supplies of columbium and tantalum during an emergency, various materials have been purchased for the NDS. The Stockpile goals, effective as of October 5, 1999, for tantalum metal powder and tantalum metal (contained tantalum) were about 16 metric tons (t) and about 55 t, respectively (table 3). The NDS had no goals for columbium materials. For fiscal year (FY) 2000 (October 1, 1999, through September 30, 2000), the DNSC sold about 182 t of columbium contained in ferrocolumbium valued at about $2.8 million, and about 9 t of columbium contained in columbium metal ingots valued at about $567,000 and disposed of about 80 t of columbium contained in tantalum minerals that were sold in FY 2000; no columbium value was obtained, as the columbium was contained within the tantalum minerals. Additionally, the DNSC sold about 2 t of tantalum contained in tantalum carbide powder valued at about $254,000, about 23 t of tantalum contained in tantalum metal powder valued at about $3.67 million, about 18 t of tantalum contained in tantalum metal ingots valued at about $3.84 million, about 134 t of tantalum contained in tantalum minerals valued at about $42.7 million, and about 9 t of tantalum contained in tantalum oxide valued at about $1.32 million. As of September 30, 2000, columbium and tantalum inventory sold but not shipped from the NDS included about 37 t of columbium contained in ferrocolumbium and about 106 t of tantalum contained in tantalum minerals (U.S. Department of Defense, 2001, p. 14, 15, 43, 45, 47, 48).

In its revised Annual Materials Plan (AMP) for FY 2001 (October 1, 2000, through September 30, 2001) and proposed AMP for FY 2002 (October 1, 2001, through September 30, 2002), the DNSC had authority to sell about 10 t of columbium contained in columbium carbide powder (actual quantity limited to the remaining sales authority or inventory), about 254 t of columbium contained in columbium concentrates, about 68 t of columbium contained in ferrocolumbium (actual quantity limited to the remaining sales authority or inventory), about 9 t of columbium contained in columbium metal ingots, about 2 t of tantalum contained in tantalum carbide powder, about 23 t of tantalum contained in tantalum metal powder (actual quantity limited to the remaining sales authority or inventory for FY 2002), about 18 t of tantalum contained in tantalum metal ingots (actual quantity limited to the remaining sales authority or inventory for FY 2002), about 227 t of tantalum contained in tantalum minerals, and about 9 t of tantalum contained in tantalum oxide (Defense National Stockpile Center, 2001a, b). For FY 2001, through June 30, 2001, the DNSC sold about 48 t of columbium contained in ferrocolumbium valued at about $1.29 million, about 9 t of columbium contained in columbium metal ingots valued at about $142,000, about 20 t of tantalum contained in tantalum capacitor-grade metal powder valued at about $14.3 million, about 18 t of tantalum contained in tantalum metal ingots valued at about $16.1 million, about 2 t of tantalum contained in tantalum carbide powder valued at about $1.34 million, and about 11 t of tantalum oxide valued at about $2.55 million.

Under the GSP, the United States grants duty-free access to eligible products from designated developing countries. In 2000, U.S. import duties for selected columbium and tantalum materials ranged from duty free to 8.5% ad valorem for normal-trade-relations (NTR) status and from duty free to 45% ad valorem for non-NTR status (U.S. International Trade Commission, 1999). In March, the GSP program, which expired on June 30, 1999, was renewed through September 30, 2001, retroactive to July 1, 1999, by a provision in the Ticket To Work and Work Incentives Improvement Act of 1999. Customs began processing refunds due to the renewal on January 7, 2000 (U.S. Customs Service, 2000). Categories of U.S. imports from developing countries affected by the GSP included all columbium and tantalum tariff articles except columbium and tantalum ores and concentrates, synthetic tantalum-columbium concentrates, and columbium and tantalum unwrought waste and scrap, for which the general rate of duty already was zero.

Production

Neither columbium nor tantalum was mined domestically in 2000. Domestic production data for ferrocolumbium are developed by the U.S. Geological Survey from the annual voluntary domestic survey for ferroalloys. Ferrocolumbium production data for 2000 were, however, incomplete at the time this report was prepared.

Cabot Performance Materials, Boyertown, PA, had production capability that ranged from raw material processing through the production of columbium and tantalum end products. In September, Cabot proceeded with the company's decision to close its Revere, PA, plant, which had produced high-purity ferrocolumbium and nickel columbium. Shieldalloy Metallurgical Corp., Newfield, NJ, was a producer of ferrocolumbium. H.C. Starck Inc. was a major supplier of tantalum and columbium products. Reading Alloys Inc., Robesonia, PA, and Wah Chang, Albany, OR, were major producers of high-purity columbium products. Kennametal Inc., Latrobe, PA, was a major supplier of columbium and

Digitized by Google

tantalum carbides (table 9).

In July, KEMET Corp., Greenville, SC, announced planned expansion of more than 7,900 square meters (m^2) of manufacturing floor space in South Carolina and Mexico dedicated to the production of solid tantalum and conductive polymer tantalum capacitors. With increasing customer demand for capacitors, KEMET, a major world maufacturer of tantalum capacitors, indicated that the capacity expansions would ensure the company's ability to provide high-value tantalum and high-frequency organic tantalum capacitors to meet its customers' needs. About 1,000 m^2 of manufacturing space would be created with additions in Mauldin and Greenwood, SC; relocation of support functions in Simpsonville, SC, would add 418 m^2; and construction of a new facility in Matamoros, Mexico, would add 6,500 m^2. The new capacity at each facility would be used to increase production rates for solid tantalum surface-mount capacitors. New capacity in Mauldin and Simpsonville would also increase production rates for KEMET's new high-performance conductive polymer tantalum capacitor. The expansions were expected to add approximately 1,100 new jobs (KEMET Corp., 2000b).

In November, KEMET announced a memorandum of understanding with Australasian Gold Mines NL (AGM) to establish a 50-50 joint venture, which would own and fund development of AGM's existing tantalum projects, including a pilot-processing plant at Dalgaranga, Australia. The feasibility of future mining and commissioning of full-scale plants would be determined. KEMET would purchase processed tantalum products from the pilot plant and any future processing development. The material would be toll converted into tantalum powder necessary for the production of capacitors. In February 2001, KEMET announced completion of the joint-venture agreement with AGM. KEMET's initial investment in the venture would be approximately $5.5 million, and KEMET would acquire a 10% interest in AGM for approximately $2.5 million. When full-scale mining operation is achieved, KEMET anticipates that the venture could ultimately provide up to 10% to 15% of its total annual tantalum requirements (KEMET Corp., 2000a; 2001).

Consumption

Overall U.S. reported consumption of columbium as ferrocolumbium and nickel columbium rose by almost 20% compared with that of 1999 (table 4). Consumption of columbium by the steelmaking industry increased by more than 10% as a result of an increase in raw steel production, with consumption up in all major reported steel end-use categories. Demand for columbium in superalloys increased significantly to more than 940 t, reflecting strong demand from the aerospace industry. That portion used in the form of nickel columbium increased to about 600 t. Overall U.S. apparent consumption of all columbium materials was estimated to be about 4,300 t, compared with about 4,100 t in 1999.

Estimated overall U.S. apparent consumption of all tantalum materials increased by more than 15% to about 650 t, owing to continued strong demand for tantalum powder for the production of tantalum capacitors. More than 60% of total tantalum consumed was in the electronics industry. Major end uses for tantalum capacitors included portable telephones, pagers, personal computers, and automotive electronics. Tantalum consumption was also affected by increased demand for tantalum-containing superalloys for jet engine and gas turbine components.

Columbium.—"Columbium" and "niobium" are synonymous names for the chemical element with atomic number 41; "columbium" was the name given in 1801, and "niobium" was the name officially designated by the International Union of Pure and Applied Chemistry in 1950. The metal conducts heat and electricity well and is characterized by a high melting point (about 2,470 °C), resistance to corrosion, and ease of fabrication.

Columbium in the form of ferrocolumbium is used worldwide, mostly as an alloying element in steels and in superalloys. Because of its refractory nature, appreciable amounts of columbium in the form of high-purity ferrocolumbium and nickel columbium are used in nickel-, cobalt-, and iron-base superalloys for such applications as jet engine components, rocket subassemblies, and heat-resisting and combustion equipment. Columbium carbide is used in cemented carbides to modify the properties of the cobalt-bonded tungsten carbide-based material. It is usually used with carbides of such metals as tantalum and titanium. Columbium oxide is the intermediate product used in the manufacture of high-purity ferrocolumbium, nickel columbium, columbium metal, and columbium carbide. Acceptable substitutes, such as molybdenum, tantalum, titanium, tungsten, and vanadium, are available for some columbium applications, but substitution may lower performance and/or cost effectiveness.

Tantalum.—The major use for tantalum as tantalum metal powder is in the production of electronic components, mainly tantalum capacitors. The tantalum capacitor exhibits reliable performance and combines compactness and high efficiency with good shelf life. Applications for tantalum capacitors include computers, communication systems, and instruments and controls for aircraft, missiles, ships, and weapon systems. Because of its high melting point (about 3,000° C), good strength at elevated temperatures, and good corrosion resistance, tantalum is combined with cobalt, iron, and nickel to produce superalloys that are used in aerospace structures and jet engine components. Tantalum carbide, which is used mostly in mixtures with carbides of such metals as columbium, titanium, and tungsten, is used in cemented-carbide cutting tools, wear-resistant parts, farm tools, and turning and boring tools. Because of tantalum's excellent corrosion-resistant properties, tantalum mill and fabricated products are used in the chemical industry in such applications as heat exchangers, evaporators, condensers, pumps, and liners for reactors and tanks. Substitutes, such as aluminum, rhenium, titanium, tungsten, and zirconium, can be used in place of tantalum but are usually used at either a performance or economic penalty.

Prices

Published prices for pyrochlore concentrates produced in Brazil and Canada were not available because these concentrates were consumed internally by producers of regular-grade ferrocolumbium and are no longer being exported. A price for Brazilian pyrochlore has not been available since 1981, and the published price for pyrochlore produced in Canada was discontinued in early 1989. The columbium price is affected most by the availability of regular-grade ferrocolumbium produced from pyrochlore. The American Metal Market published price for regular-grade ferrocolumbium ranged from

Digitized by Google

$6.75 to $7 per pound of contained columbium and has not changed since September 1997.

The Metal Bulletin price for columbite ore, which is based on a minimum 65% contained columbium oxide (Nb_2O_5) and tantalum oxide (Ta_2O_5), quoted since February 1995 at a range of $2.80 to $3.20 per pound, rose to a range of $5.50 to $7 in late November, where it remained through December. The American Metal Market published price for high-purity (vacuum-grade) ferrocolumbium ranged from $17.50 to $18 per pound of contained columbium and has not changed since September 1997. Industry sources indicated in December 1999 that nickel columbium sold at about $18.50 per pound of contained columbium, columbium metal products sold in the range of about $24 to $100 per pound in ingot and special shape forms, and columbium oxide for master alloy production sold for about $8.80 per pound (Mining Journal, 1999a; Tantalum-Niobium International Study Center, 1999a, p. 5). Significant events affecting columbium prices since 1958 include the following: 1960-70, development of pyrochlore deposits in Brazil and Canada; 1970-79, increased demand and rising prices; 1980, columbium oxide produced from pyrochlore-based feed material; 1981, exports of Brazilian pyrochlore ceased; 1994, production of ferrocolumbium began in Canada; 1997-98, sales of ferrocolumbium from the NDS; and 1998, expansion of ferrocolumbium production capacity in Brazil (Cunningham, 1999a).

The price for tantalum products is affected most by events in the supply of and demand for tantalum minerals. During 2000, published prices for tantalite ore (per pound contained oxide) rose significantly: Platt's Metals Week, rose to a range of $145 to $175 from a range of $33 to $35; Metal Bulletin, rose to a range of $180 to $240 from a range of $28 to $31.50; and Ryan's Notes, rose to a range of $250 to $300 from a range of $45 to $48. Strong global demand and an apparent shortage of tantalum source materials for processing contributed to the price increase. In 2000, sales of tantalum minerals from the NDS averaged about $118 per pound contained tantalum oxide. In July 2001, published prices for tantalite ore (per pound contained oxide) were as follows: Platt's Metals Week, a range of $75 to $100; Metal Bulletin, a range of $55 to $75; Ryan's Notes, a range of $48 to $55. The decrease in price reportedly was due in part to excess tantalum inventories and a downturn in tantalum demand from the electronics sector. The Metal Bulletin published price for Greenbushes tantalite ore, Australia, was $40 per pound contained oxide and has not changed since April 1991. The most recent industry source (August 1999) on tantalum product prices indicated that the average selling prices per pound of contained tantalum for some tantalum products were as follows: capacitor-grade powder, $135 to $260; capacitor wire, $180 to $270; and vacuum-grade metal for superalloys, $75 to $100 (Mining Journal, 1999b). Presumably these prices increased in 2000, based on the escalating price for tantalum ore, but public information on prices for these products was not available. Significant events affecting tantalum prices since 1958 include the following: 1979-80, tantalum price accelerates to record levels; 1982, industry's accumulation of large tantalum material inventories; 1988, drawdown of tantalum material inventories by processors; 1990, purchase of tantalum materials for the NDS; 1991, long-term tantalum supply contracts between major producer and processors; and 1998, sales of tantalum minerals from the NDS (Cunningham, 1999b).

Foreign Trade

Table 5 lists columbium and tantalum export and import data. Net trade for columbium and tantalum continued at a deficit. Overall trade value for exports increased significantly with total volume down slightly. In descending order, Israel, the United Kingdom, Japan, Germany, and China were the major recipients of the columbium and tantalum materials, on the basis of value, with more than 80% of the total. For imports, overall trade value was up by about 35%, with total volume up by more than 10%. In descending order, Brazil, Japan, Australia, China, Germany, and Canada were the major sources of columbium and tantalum imports, on the basis of value, with more than 70% of the total.

Imports for consumption of columbium ores and concentrates increased by about 60% (table 6); imports from China accounted for more than 20% of quantity and value. Imports at an average grade of approximately 30% Nb_2O_5 and 31% Ta_2O_5 were estimated to contain about 30 t of columbium and about 40 t of tantalum. Ferrocolumbium and columbium oxide imports were down slightly; Brazil accounted for more than 80% of U.S. ferrocolumbium imports and about 40% of columbium oxide imports.

Imports for consumption of tantalum ores and concentrates increased twofold (table 7); imports from Australia accounted for more than 60% of quantity and about 55% of value. Imports at an average grade of approximately 37% Ta_2O_5 and 18% Nb_2O_5 were estimated to contain about 610 t of tantalum and about 270 t of columbium.

The schedule of tariffs applied during 2000 to U.S. imports of selected columbium and tantalum materials is found in the Harmonized Tariff Schedule of the United States—2000 (U.S. International Trade Commission, 1999). Brazil, which was the major source for U.S. columbium imports, accounted for about 68% of total, in units of contained columbium (figure 1), and Australia, which was the major source for U.S. tantalum imports, accounted for about 48% of total, in units of contained tantalum (figure 2).

Net import reliance as a percent of apparent consumption is used to measure the adequacy of current domestic columbium and tantalum production to meet U.S. demand. For columbium in 2000, net import reliance as a percent of apparent consumption was 100%. For tantalum, net import reliance as a percent of apparent consumption was estimated to be about 80%.

World Review

Industry Structure.—Principal world columbium and tantalum raw material and product producers are listed in tables 8 and 9, respectively. Annual world production of columbium and tantalum mineral concentrates, by country, is listed in table 10. Brazil and Canada were the major producers of columbium mineral concentrates, and Australia, Brazil, Canada, and Congo (Kinshasa) were the major producers of tantalum mineral concentrates. The importance of tantalum-containing tin slags as a source of tantalum supply has decreased owing to structural changes in the tin industry. Tantalum-containing tin slags account for about 18% of tantalum supply compared with about 70% 20 years ago (Mining Journal, 2000b; Tantalum-Niobium International Study Center, 1998, p. 2-6).

Australia.—For its 1999-2000 financial year ending June 30,

Digitized by Google

2000, Sons of Gwalia Ltd., West Perth, Western Australia, reported that tantalum production (tantalum oxide contained in mineral concentrates) totaled about 505 t at its Greenbushes and Wodgina Mines and that tantalum sales totaled about 500 t. Greenbushes production was about 315 t, and sales, about 314 t. Production at Wodgina was about 190 t, and sales, about 186 t. Existing "main production" at Greenbushes will be exhausted in 1993. Annual production capacity at Greenbushes is planned to be expanded from about 320 t to about 590 t. The existing processing facility will be expanded from about 1.6 million metric tons (Mt) of ore to more than 2.75 Mt. Preproduction capital cost for underground development at the mine, and capital cost for expansion of the existing processing facilities, total about $65 million. At Wodgina, annual production capacity will be increased over the next 2 years to more than 450 t, with plant processing capacity increasing to at least 2 Mt of ore. Capital cost for the Wodgina expansion will be approximately $35 million. By 2003, total company annual sales of contained tantalum oxide were expected to build to at least about 1,040 t. Forecast production increases from development of an underground operation at Greenbushes and the plant expansions at Greenbushes and Wodgina were expected within 3 years, with construction activities scheduled to commence in early 2001. Greenbushes existing production and the increased production from the Wodgina expansion were committed to Cabot Corp. and H.C. Starck of Germany under long-term contracts through to calender year 2005 (Sons of Gwalia Ltd., 2000, p. 7, 22-26).

In its quarterly report for March 31, 2001, Sons of Gwalia reported that Greenbushes tantalum "resource base" was about 44,000 t of contained tantalum oxide, including about 20,400 t classified as tantalum reserves. As a result of a successful drilling program, Wodgina's tantalum "resource base" doubled to about 27,200 t of contained tantalum oxide, including about 24,000 t classified as tantalum reserves (Sons of Gwalia Ltd., 2001, p. 9, 10).

Brazil.—Cia. Brasileira de Metalurgia e Mineração (CBMM), which was the world's largest columbium producer, completed its $80 million expansion program that was initiated in 1998. Annual columbium ore concentration capacity was increased to about 84,000 t of concentrate, and annual ferrocolumbium capacity increased to about 45,000 t. The new concentration plant uses a pyrometallurgical process, which replaced a leaching plant. In 2000, CBMM was expected to produce about 51,000 t of concentrate, about 30,000 t of ferrocolumbium, and about 2,000 t of columbium oxide for use in the aerospace industry. In 1999, CBMM reportedly produced about 40,000 t of concentrate and about 25,000 t of ferrocolumbium. For 2001, CBMM planned to increase concentrate output to about 55,000 t and to increase ferrocolumbium output to about 33,000 t. CBMM was said to export 95% of its ferrocolumbium production, mostly to Europe and North America, 35% each, and to Japan, 16% (American Metal Market, 2000; TEX Report, 2000).

Canada.—Production of columbium oxide contained in pyrochlore concentrate at the Niobec Mine near Chicoutimi, Quebec, was about 3,270 t compared with about 3,370 t in 1999. Niobec was a 50-50 joint venture between Cambior Inc. (product marketing), and Teck Corp. (operator). Columbium contained in ferrocolumbium production was about 2,170 t compared with about 2,290 t in 1999. Pyrochlore-to-ferrocolumbium converter recovery was 96.2% compared with 97.1% in 1999. Ore milled increased to 907,000 t as the mill operated, on the average, at about 2,480 metric tons per day. Average recovery decreased to 54.6%, with the Nb_2O_5 grade of concentrate at 66%. Operating cost, dollars per metric ton of ore milled, was about $37.30 compared with about $36.10 in 1999. Capital expenditures were $9 million, including $7 million for expansion of mill and converter capacities. For 2001, capital costs were forecast at $3 million, including $2 million for underground development and equipment. Teck reported proven and probable ore reserves of 11.5 Mt grading 0.51% columbium. In November, Teck reached an agreement to sell its 50% interest in Niobec to Mazarin Inc., Quebec, for $47 million. The transaction was expected to be closed in the first half of 2001, with Teck expecting to record a pretax gain of $25 million on the sale (Cambior Inc., 2001, p. 11; Teck Corp., 2001, p. 24, 32, 58). As part of its financial restructuring, Cambior entered into an agreement with Jipangu Inc., a Japanese investment company, and a financial institution for a mortgage loan on its 50% interest in Niobec for $13 million. The term was for 4.5 years repayable in 16 consecutive quarterly installments commencing on March 30, 2001, with a maturity date of December 31, 2004. The mortgage was secured by Cambior's 50% interest in Niobec and its share of the cash flow generated by the mine. On January 18, 2001, Jipangu agreed to a $6.3 million private placement to subscribe to 15 million common shares of Cambior at a price of $0.42 per share, with proceeds from the private placement used to repay in part Jipangu's mortgage loan (Cambior Inc., 2001, p. 24, 25, 37).

In 2000, about 69 t of tantalum oxide contained in concentrate was produced at the Bernic Lake, Manitoba, tantalum operation, compared with about 66 t in 1999.

In October, it was reported that Avalon Ventures Ltd., Toronto, had finalized a joint-venture agreement with Global Canada Co., a private Nova Scotia company controlled by BSAV Inc., a private Delaware company. Global would have the right to earn up to 75% interest in any of Avalon's Canadian tantalum exploration properties, Lilypad Lakes, Raleigh Lake, and East Braintree. Global would have the right to earn an initial 50% interest in any of the properties by providing $5 million in exploration and development funding before December 31, 2002, or upon delivery of a feasibility study. The interest in any one property could be increased to 75% by Global arranging financing to bring a tantalum mine into production. Initial commitment by Global was to provide $1 million to fund work programs on the properties and to provide working capital. The program had a budget of $750,000 to be spent by December 31, 2000. Avalon would be the operator of the exploration programs, and Global would have the right to participate in any other tantalum exploration properties acquired by Avalon in Canada. Lilypad Lakes near Pickle Lake, Ontario, had top priority with a program budget of $580,000. A preliminary diamond drilling program completed in April intersected tantalum mineralization occurrences averaging 0.05 % Ta_2O_5 across 11.5 meters (m), 0.036% Ta_2O_5 across 24 m, and 0.076% Ta_2O_5 across 7 m. In addition, a surface program involving mapping, sampling, lithogeochemistry, and a gravity survey discovered a new high-grade tantalum occurrence. Assays of 10 random samples indicated tantalum ranging from 0.131% to 0.422% Ta_2O_5. A minimum 1,100-m diamond drilling program was scheduled to begin on the property in November (Avalon Ventures Ltd., 2000a, b;

Digitized by Google

Skillings Mining Review, 2000).

China.—China's Jiujiang Nonferrous Metals Smelter, eastern Jiangxi Province, completed an upgrade to its tantalum production line which increased annual production capacity to about 20 t from 2 t to 3 t. Existing production ceased in January and new production started in mid-August. However, owing to raw material shortages, output was expected to reach only about 4 t by January 2001. Jiujiang's annual columbium production capacity was about 20 t, with output in 2000 expected to be about 15 t. Annual production capacity for tantalum oxide and columbium oxide was about 100 t and 300 t, respectively, with tantalum oxide output in 2000 expected to be about 70 t and columbium oxide output about 100 t. In 1999, tantalum oxide output was about 60 t and columbium oxide output about 100 t (Platt's Metals Week, 2000).

Congo (Kinshasa).—In June, the President of the Security Council, United Nations, requested the Secretary-General to establish a panel of experts on the illegal exploitation of natural resources and other forms of wealth of the Democratic Republic of the Congo for a period of 6 months. The report of the panel was transmitted to the President on April 12, 2001. The panel's recommendations revolved around six broad themes: "(1) sanctions against countries and individuals involved in the illegal activities; (2) preventive measures to avoid a recurrence of the current situation; (3) reparations to the victims of the illegal exploitation of natural resources; (4) design of a framework for reconstruction; (5) improvement of international mechanisms and regulations governing some natural resources; and (6) security issues." Categories that were of primary consideration included coltan (columbium and tantalum). Some of the panel's recommendations for Security Council action included an immediate temporary embargo on the import or export of coltan and pyrochlore; the freezing of financial assets of the rebel movements and their leaders; the freezing of financial assets of the companies or individuals who continue to participate in the illegal exploitation of the natural resources of the Congo immediately after publication of the report; and the declaration of an immediate embargo on supply of weapons and all military material to rebel groups operating in Congo (United Nations, 2001).

Greenland.—Angus and Ross plc, a United Kingdom company with tantalum interest in Ireland, received a licence from the Greenland Government for rights to explore for tantalum in southern Greenland centered in an area 20 kilometers east of the southern capitol of Narsarsuaq. The area of interest is the Motzfeld Centre, an alkaline igneous ring complex, with pyrochlore the most important economic mineral phase. Data suggest that resources could be about 50 Mt of ore grading in the range of 0.03% to 0.1% Ta_2O_5, and about 130 Mt of ore grading in the range of 0.4% to 1% Nb_2O_5, with some zones in the range of 1% to 1.5% Nb_2O_5. Mineralogy of the area was said to be complex and mineral processing problems remain to be addressed (Mining Journal, 2000a).

Japan.—In 2000, Japan's demand for tantalum was about 552 t; powder, 269 t; compounds,157 t; and products, 126 t. Demand for tantalum powder was met by imports from China, Thailand, the United States, and domestic production from imported potassium fluotantalate. Imports of potassium fluotantalate totaled about 1,140 t, sufficient for the production of about 378 t of tantalum powder. Production of tantalum powder for the electronics sector was about 386 t. Demand for tantalum wire used in tantalum capacitors was met entirely by imports, about 68 t, mostly from the United States. Tantalum imports (powder, compounds, and products) in 2000 were about 139 t compared with about 98 t in 1999. In 2000, apparent consumption of tantalum powder, wire, and products was 269 t, 69 t, and 57 t, respectively. In 2001, tantalum demand is forecast to fall to about 462 t; powder, 225 t; compounds, 127 t; and products, 110 t (Roskill's Letter from Japan, 2001b). Tantalum scrap imported for the production of tantalum powder, compounds, and products was about 203 t; Portugal, the United Kingdom, and the United States accounted for about 75% of the imports. In 2000, Japan's production of tantalum capacitors totaled about 8.67 billion units compared with about 6.54 billion units in 1999. Tantalum capacitor exports in 2000 were about 3.24 billion units compared with about 2.56 billion units in 1999 (Roskill's Letter from Japan, 2001a).

Russia.—At yearend 1999, the Chita region made a decision to join a federal program named Libton for the creation of a scientific production center for rare metals, including tantalum, in the Trans-Baikal region. The Chita region and TVEL, a producer and supplier of nuclear fuel controlled by the Russian Ministry of Atomic Energy, signed an agreement on liaison with the Priargunsky Mining and Chemicals Production Association, a uranium producer controlled by TVEL, and the Zabaikalsky Mining and Beneficiation Plant, a rare metal producer. The Ministry was to finance the program and coordinate efforts by Priargunsky and Zabaikalsky to produce materials for the nuclear sector (Interfax International Ltd., 2000).

Outlook

Columbium.—The principal use for columbium will continue as an additive in steelmaking, mostly in the manufacture of microalloyed steels used for pipelines, bridges, automobiles, etc. The production of high-strength low-alloy steel is the leading use for columbium, and the trend for columbium demand, domestically and globally, will continue to follow closely that of steel production (see the "Outlook" section of the Iron and Steel chapter for a discussion of the future of the steel industry). The October 2000 medium-term forecast of the International Iron and Steel Institute projected an annual growth rate in steel consumption between 2000 and 2005 for the world of 2%; the North American Free Trade Agreement countries, 0.9%; European Union countries, 0.8%; China, 3.8%; and total Asian countries, 2.6%. Japan was the only major steel consumer where steel usage was expected to fall, by about 1% (International Iron and Steel Institute, October 3, 2000, IISI survey reveals renewed world steel consumption growth—Annual report of the Secretary General, accessed June 1, 2001, at URL http://www.worldsteel.org/trends_indicators/demand.html).

The outlook for columbium also will be dependent on the performance of the aerospace industry and the use of columbium-bearing alloys in it. Columbium consumption in the production of superalloys, which is the second largest end use for columbium, will be most dependent on the market for aircraft engines. Because nickel-base superalloys (such as alloy 718, which contains about 5% columbium) can account for about 40% to 50% of engine weight, they are expected to be the materials of choice for the future owing to their high temperature operating capability (Tantalum-Niobium International Study Center, 1999b). The Aerospace Industries Association (2001, p. 3) forecast that U.S. aerospace industry

Digitized by Google

sales will rise to $145 billion in 2001 from $144 billion in 2000 owing to the strength of Department of Defense increases.

The majority of U.S. demand for columbium units will continue to be met by imports. Brazil will continue as the leading source for U.S. imports of columbium, and Canada will also be a major source of supply.

Tantalum.—U.S. apparent consumption of tantalum totaled about 650 t in 2000 compared with about 555 t in 1999. More than 60% of the tantalum consumed was used to produce electronic components, mainly tantalum capacitors. This market sector is expected to be stimulated by the growth in the use of cellular telephones; each phone may contain from 10 to 20 capacitors (Mining Journal, 2000b). Tantalum consumption in superalloys, mostly in the aircraft industry, is expected to grow by about 3% per year. Tantalum carbide in the metal cutting industry and tantalum in the chemical processing industry will be dependent on the growth of the general economy, and both are expected to grow at an estimated 2% per year (Tantalum-Niobium International Study Center, 1998).

In 2000, world tantalum supply was estimated to be about 1.8 Mt of contained tantalum. For 2001, world tantalum supply was projected to be about 2.1 Mt of contained tantalum. World tantalum supply will come mostly from Australia, Brazil, Canada, China, Southeast Asia, and certain African countries (including Burundi, Congo (Kinshasa), Ethiopia, Mozambique, Nigeria, Rwanda, Uganda, and Zimbabwe) (Tantalum-Niobium International Study Center, 2001). Another important component of world supply is the U.S. Government sales of tantalum materials from the NDS. As of June 30, 2001, tantalum materials authorized for disposal from the NDS totaled about 910 t of contained tantalum, including about 860 t contained in tantalum minerals.

r/ Revised. NA Not available. -- Zero.

1/ World totals and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Excludes columbium- and tantalum-bearing tin ores and slags. Production of tantalun contained in tin slags was, in metric tons: 1996--82; 1997--40; 1998-2000--NA according to data from the Tantalum-Niobium International Study Center. Table includes data available through July 9, 2001.

3/ Data on gross weight generally have been presented as reported in official sources of the respective countries, divided into concentrates of comlumbium, tantalite, and pyrochlore where information is available to do so, and reported in groups, such as columbite and tantalite, where it is not.

4/ Unless otherwise specified, data presented for metal content are estimates based on, in most part, reported gross weight and/or pentoxide content.

5/ In addition to the countries listed, Bolivia, China, Russia, and Zambia also produce or are believed to produce columbium and tantalum mineral concentrates, but information is inadequate to make reliable estimates of output levels.

6/ Reported figure.

COPPER

By Daniel L. Edelstein

Domestic survey data and tables were prepared by Janet D. Richards and Deana Demichelis, statistical assistants, and the world production tables were prepared by Regina R. Coleman, Linder Roberts, and Glenn J. Wallace, international data coordinators.

In 2000, mine production of recoverable copper in the United States continued its downward slide that began in 1998, falling by more than 150,000 metric tons (t) to the lowest level since 1988. In addition to mine closures and cutbacks carried forward from midyear 1999, high energy costs coupled with low copper prices led to unanticipated cutbacks and closures. Some rationalization of capacity occurred following consolidation of ownership at the end of 1999. Three companies, Phelps Dodge Corp., ASARCO Inc. (owned by Mexico's Grupo Mexico S.A. de C.V.), and Kennecott Utah Copper Corp. (owned by Rio Tinto plc of the United Kingdom), accounted for more than 95% of U.S. copper mine production.

While the United States maintained its position as the world's second largest mine producer of copper, accounting for about 11% of world production, its share of global production continued to decline from its 19% share in 1994. Chile, where mine production increased by 5% in 2000, and by 85% since 1995, was the largest mine producer and accounted for 35% of world production. World mine production grew by about 3.5% in 2000 and by 30% since 1995. The world reserves and reserve base for copper were estimated to be 340 million metric tons (Mt) and 650 Mt, respectively. The United States had about 13% each of reserves and reserve base. In the 1998 National Mineral Resource Assessment conducted by the U.S. Geological Survey (U.S. Geological Survey, 2000), the estimated copper contained in undiscovered resources in the United States ranged from greater than 170 Mt at a 90% probability to greater than 440 Mt at a 10% probability. The mean estimate of copper in undiscovered deposits was 290 Mt. According to the assessment, more than two-thirds of the copper was thought to be contained in undiscovered porphyry copper deposits. Other major deposit types were sediment-hosted and volcanogenic massive sulfide deposits. About 50% of the undiscovered resource was believed to be in Great Basin and Southern Basin and Range regions (portions of Arizona, California, Nevada, New Mexico, and Utah). The identified copper resource was estimated to be 260 Mt. Coupled with past production of about 91 Mt, the total discovered copper resource in the United States was estimated to be 350 Mt.

U.S. copper smelter and refinery production also continued to fall and were down by 23% and 16%, respectively, from 1999 production levels, and 42% and 33%, respectively, from production in 1998. Owing to the combined impact of mine cutbacks and low prices, three of seven primary smelters had closed in 1999. Primary refined production declined owing to a downstream shortage of anode for refining. With the three smelters remaining closed in 2000, the United States became a net exporter of copper in concentrates. Contraction of the secondary copper industry continued with the closure in May of one of the Nation's two remaining secondary smelters and its

Copper in the 20th Century

At the beginning of the 20th century, following patenting of the electric lightbulb and initial development of electric power distribution infrastructure late in the 19th century, the United States was experiencing a prolonged period of expansion in copper use for electrical generation, distribution, and industrial applications. U.S. mine production rose from 27,000 metric tons in 1880 to 275,000 tons in 1900 and 490,000 tons in 1910. Most of the copper produced came from high-grade vein deposits that predominantly yielded ore for direct shipping to smelters (80 smelters operated in 1907). By 1900, Montana and Arizona had emerged as the leading producing States, accounting for 45% and 20% of domestic production, respectively. The United States was by far the world's largest producer in 1900, accounting for 55% of world production and exporting about 160,000 tons of refined copper and consuming about 160,000 tons.

The United States retained its position as the largest producer and consumer of copper through most of the century. Domestic copper mine production peaked in 1997 at 1.94 million tons. Froth flotation and large-scale open pit mining methods introduced during the first decade of the century had revolutionized copper mining, and production was derived increasingly from low-grade porphyry copper deposits. Industrialization, rural electrification, and growing infrastructure all contributed to the growth in copper demand. Electrical applications accounted for an increasing share of domestic consumption (about 75% in 2000).

By the start of the 21st century, however, the United States had relinquished its role as the world's largest copper producer to Chile (35% of global production). U.S. mine production in 2000 fell to about 1.4 million tons and accounted for only about 11% of world production. Technology advances made in the 1980s resulted in one-third of U.S. mine output in 2000 coming from the leaching and solvent extraction-electrowinning of acid soluble ores. The combined impact of environmental regulation and industry restructuring left only four smelters operating. The United States remained the world's largest user of refined copper (about 3 million tons, 20% of world total) and was dependant on imports for about one-third of its refined copper supply. Copper recovered from old scrap (500,000 tons in 1997) also fell victim to industry consolidation and offshore processing and declined to only 350,000 tons in 2000.

Digitized by Google

captive electrolytic refinery. Electrowon production, which accounted for a record 36% of primary refined production and 38% of mine production, declined by about 5%. Though it retained its position as the second largest refiner and third largest smelter, the U.S. share of world smelter and refinery production fell to 9% and 12% , both down from 15% in 1998. In 1998, the United States had been the largest smelter and refiner of copper.

Twenty-seven mines operating in 7 States, down from 33 in 1999, reported recoverable quantities of copper in 2000. Fourteen mines located in Arizona, Utah, New Mexico, and Montana, in descending order, accounted for more than 99% of production. The remaining 13 mines were either small leach operations or byproduct producers of copper. Despite the decline in production, capacity utilization at domestic mines rose, as capacity was adjusted downward to reflect the long-term closure of mines that were not expected to reopen without significant capital investment.

During the year, 4 primary and 2 secondary smelters, 6 electrolytic and 3 fire refineries, and 14 solvent extraction-electrowinning (SX-EW) facilities operated in the United States. By yearend, however, one secondary smelter and associated electrolytic refinery had closed. Following closure of three primary smelters in 1999, which were not anticipated to reopen in the short term, smelter capacity for 2000 was revised downward from 1.75 million metric tons per year (Mt/yr) in 1999 to 1.18 Mt/yr. Consequently, smelter capacity utilization rose from 74% in 1999 to 85% in 2000. Capacity at refineries declined by about 200,000 metric tons per year (t/yr) to 2.4 Mt/yr and the utilization rate fell to 74%. The conversion of old scrap to alloys and refined copper, declined by 47,000 t (12%), contributed 334,000 t of copper to the market, and accounted for 11% of apparent industrial demand. Lower copper prices in 2000 and closure of a secondary copper smelter led to the continued downward trend in recovery.

Copper was consumed as refined copper and as direct melt scrap at about 35 brass mills, 13 wire-rod mills, and 600 foundries, chemical plants, and miscellaneous operations. According to data compiled by the Copper Development Association Inc. (CDA) (Copper Development Association, Inc., 2001, p. 18), mill and foundry product shipments to the U.S. market, including net imports of mill products, continued their upward trend, rising by170,000 t (4%) to 4.33 Mt, and were 43% higher than shipments in 1990.

The net import reliance for refined copper, as a percentage of apparent consumption, rose sharply to a record-high 37% (from 14% in 1998) following cutbacks in domestic production and growth in demand. Peru emerged as the largest source of refined copper, and, along with Canada and Chile, accounted for about 80% of refined imports. Canada remained the largest U.S. source for unwrought copper, accounting for 27% of total imports of unwrought copper. China (including Hong Kong), owing to a large growth in U.S. scrap exports, became the largest recipient for unwrought exports, accounting for 58% of refined exports and 38% (copper content) of total exports.

Legislation and Government Programs

On January 26, 2000, as authorized by the Coin Act of 1997, the U.S. Mint began releasing its new Golden dollar coin to replace the Susan B. Anthony dollar coin that had been introduced in 1979. In its report to Congress, the Mint outlined details of a promotional campaign aimed at helping the public build a strong awareness for the coins. According to the Mint, about 700 million Golden Dollars were placed in circulation during 2000, 7 times initial expectations. The new coins also generated an $800 million profit for the Mint (U.S. Mint, 2001). At a coin weight of 8.1 grams and overall composition of 88.5% copper, 6% zinc, 3.5% manganese, and 2% nickel, the 700 million coins contained about 5,000 t of copper.

In January, the U.S. Department of Labor, Division of Trade Adjustment and Assistance, rejected a petition by the United Steel Workers of America seeking transitional adjustment assistance for workers producing copper rod at the Pauline, KS, plant of Superior-Essex Inc. In rejecting the petition, the department found that criterion 3 (the subject firm increased imports of like products from Canada or Mexico) and criterion 4 (the firm shifted production to Canada or Mexico) of the act had not been met. The Division of Trade Adjustment and Assistance concluded that copper rod production at Pauline had been shifted to other domestic plants of the subject firm and that Superior-Essex had neither increased its imports from Mexico or Canada nor shifted production to those countries (U.S. Department of Labor, 2000).

In June, the U.S. Environmental Protection Agency (EPA) proposed a change to its proposed national emissions standards for hazardous air pollutants (NESHAP) for primary smelters (smelting furnaces, slag cleaning furnaces, and batch converters). In April 1998, under section 112 of the Clean Air Act, which directs EPA to establish NESHAPs to control emissions from major stationary sources, EPA had proposed an equipment-based standard. The new proposed rule for the control of process emissions would establish a numerical emissions standard for particulate matter of 23 milligrams of total particulate matter per dry standard cubic meter (0.010 grains per dry standard cubic foot). In EPA's judgment, the proposed standard reflects "a level of total particulate matter emissions that can be achieved consistently by a properly operated and maintained sulfuric acid plant used to control process offgas from primary smelting and converting operations." The proposed standard also specifies that a furnace will be in violation of the standard if leak detector alarms installed on baghouses indicate higher than allowable emissions more than 5% of the operating time over a 6-month period. Copper smelting was 1 of 170 categories selected for regulation under the Clean Air Act (U.S. Environmental Protection Agency, 2000b).

In November, in response to an industry petition, EPA issued a final rule exempting the need for a residue tolerance test, in accordance with the Federal Food, Drug, and Cosmetic Act (as amended by the Food Quality Protection Act of 1996), when copper sulfate pentahydrate is used as a fungicide on raw agricultural commodities after harvest. This regulation eliminates the need to establish a maximum permissible level for residues of copper sulfate pentahydrate. While use of copper compounds has been exempted from tolerance tests when applied to growing crops, they had not been exempted when applied to crops at the time of or after harvest. Copper compounds are already exempted from testing when used on harvested fish, meat, poultry, eggs, and irrigated crops. In granting its exception, EPA noted relevant scientific data indicating that it is unlikely that excessive amounts of copper

Digitized by Google

ion from this use would be ingested, that copper is ubiquitous in nature and naturally occurring in ingested water and plants, is an essential nutritional element in animals (including humans) and plants, not readily absorbed when ingested, and that most of absorbed copper is excreted (U.S. Environmental Protection Agency, 2000a).

Production

Mine production capacity was adjusted downward by about 250,000 t/yr to about 1.75 Mt/yr, reflecting the sustained closure of BHP Copper Co. mines and reduced capacity at several other mines that had shifted mining strategies or plans. Phelps Dodge closed its Metcalf concentrator at its Morenci Mine in Arizona during August in anticipation of switching to an all leach operation in 2001. In response to lower average prices, mine closures, and higher than anticipated utility rates, production declined by about 160,000, t and capacity utilization rose slightly to about 84%. With the exception of its small Arizona leach SX-EW operations at San Manuel, Pinto Valley, and Miami, BHP's mines remained shuttered.

Primary smelter production declined by 21% following the closure of three of the seven primary domestic smelters during 1999 and was down by 42% from that in 1998. Smelter capacity was revised downward to reflect the indefinite closure of these smelters. Secondary smelter production continued its downward trend, declining by 31%. In May, Southwire Co. closed its secondary smelter and associated electrolytic refinery, in Carrollton, GA. Southwire continued to operate its rod mill housed within its Copper Division Southwire (CDS). Sixteen months prior, as part of a restructuring plan aimed at lowering its costs, Southwire had unsuccessfully placed its Carrollton copper smelter/refinery operations on the market. Southwire cited economic factors, including the continued cost of compliance with environmental regulations in the metro-Atlanta area, for the closure of copper smelting operations. CDS was constructed in 1972, at a time when primary producers exerted greater control over copper prices. As part of the closure justification, Southwire cited the advent of worldwide commodity prices and their own "strong buying position" as leverage in meeting future raw material needs (Southwire Co., 2000). Closure of CDS secondary copper facilities, which have a capacity to produce 140,000 t/yr of refined copper, had a significant impact on the U.S. scrap copper market. Southwire processed a mixture of imported blister and copper scrap at its smelter to produce anode for electrolytic refining. Southwire was one of two remaining secondary smelters in the United States, two other smelters having closed in the preceding 3 years. Southwire closed its other secondary copper smelter in Gaston, SC, at the end of 1994, also citing the high cost of environmental compliance as the reason for closure.

Primary and secondary refinery production declined by 16% and 9%, respectively. The aforementioned smelter closures led to downstream shortages of anode for refining. Electrowon production declined by only about 3% and accounted for a record 36% of primary refined production. The Warrenton fire refinery, which had closed in March 1999, was reopened under different management, mitigating some of the lost secondary refinery capacity.

Following acquisition of the assets of Cyprus Amax Minerals Co. at yearend 1999, Phelps Dodge Corp. reported record copper production of 1.32 Mt, including minority participants share of 235,000 t, from its worldwide operations. U.S. production amounted to 850,000 t. In the United States, production and costs were adversely affected by unusually heavy precipitation during the fourth quarter of the year and high energy costs, including electricity, diesel fuel, and natural gas. According to Phelps Dodge, its domestic electricity costs during the fourth quarter averaged $0.11 per kilowatthour, more than three times their 5-year average cost, and total energy costs rose by $0.08 per pound of copper production, a 65% increase over the comparative 1999 period. Total energy costs increased copper unit costs in 2000 by approximately $0.04 per pound compared with unit costs in 1999. Beginning in the spring of 2000, the impact of a power supply/demand imbalance in California, drought in the Pacific Northwest, and higher natural gas prices caused a shortage of electricity and higher spot market electricity costs. Approximately 27% of Phelps Dodge's electricity requirements in 2000 was purchased on the spot market (Phelps Dodge Corp., 2001a, p. 15-16; 2001b, p. 3).

At its Morenci Mine, production of copper in concentrate declined from 177,000 t to 120,000 t following placement of the Metcalf concentrator on standby in June. In September 1999, Phelps Dodge had announced its intent to reduce production costs by converting all Morenci production to mine-for-leach by early 2001 and permanently shut both the Metcalf and Morenci concentrators. The $220 million conversion proceeded throughout 2000 and was completed during the first quarter of 2001. New facilities included an expanded crushing and conveying system, mobile stackers to disperse the ore on leach piles, expanded solvent extraction facilities, and construction of a new electrowinning tankhouse. Electrowon production in 2000 of 258,000 t was unchanged from that of 1999 (Phelps Dodge Corp., 2001a, p. 3-9).

At its Miami, AZ, leach operations acquired with the purchase of Cyprus Amax, a new mine plan was instituted in June that suspended stripping in a higher cost section of the mine and allowed redistribution of equipment to other Phelps Dodge operations. Production in 2000 of 54,000 t of cathode was not impacted by the mine plan change, though production in 2001 and 2002 was expected to fall by 16,000 t and 39,000 t, respectively. At its newly acquired Bagdad Mine in Arizona, Phelps Dodge reported production of 101,000 t of copper in concentrate and 10,700 t of electrowon copper. Electrowon production at its Tyrone, NM, mine was essentially unchanged at 72,000 t (Phelps Dodge Corp., 2001a, p. 3-9).

In March, Phelps Dodge ended speculation on the fate of its newly acquired Sierrita Mine in Arizona when it announced that it intended to invest $13 million to upgrade the mine ($2.9 million), the crushing and conveying system ($2.5 million), the solvent extraction circuit ($1.3 million), as well as other upgrades and land purchases ($3.0 million) (Platt's Metals Week, 2000c). Production in 2000 amounted to 87,000 t of copper in concentrate and 24,000 t of electrowon copper (Phelps Dodge Corp., 2001a, p. 8).

At its Hidalgo, NM, smelter, closed in September 1999, Phelps Dodge announced its intention to reconfigure the smelter to produce sulfuric acid for its leaching operations. While Phelps Dodge had a near-term surplus of concentrate, the company announced at midyear that it intended to stop exporting surplus concentrates and to stockpile them in anticipation of conversion of Morenci to all leach operation,

Digitized by Google

resulting in a future concentrate shortfall. Prior to closure of the Hidalgo smelter, Phelps Dodge had been a net importer of copper concentrates from its South American operations (Phelps Dodge Corp., 2000). In 2000, Phelps Dodge smelters produced 449,000 t of copper. As a result of the upstream curtailment in smelting, Phelps Dodge's refineries in El Paso, TX, and Miami, AZ, operated at only 72% of their combined capacity, producing 427,000 t of copper cathode (Phelps Dodge Corp., 2001a, p. 9).

In July, Asarco, a wholly owned subsidiary of Mexico's Grupo Mexico S.A. de C.V., announced plans to consolidate all corporate functions in Phoenix, AZ, by yearend. Following acquisition by Grupo in November 1999, Asarco had already transferred many of its corporate functions from New York City to Arizona (ASARCO Inc., 2000a). Grupo reported that operating and cost savings from the integration of Asarco and Southern Peru Copper Corp. following acquisition in 1999 amounted to more than $171 million. Asarco's share of mine production declined from 293,000 t in 1999 to 261,000 t in 2000 (Grupo Mexico S.A. de C.V., 2001b).

At Asarco's Ray Operations in Hayden, AZ, production of copper in concentrate and electrowon cathode declined to 99,300 t and 38,800 t, respectively, down from 144,000 t and 40,000 t, respectively, in 1999. The Ray mining unit consists of a 227,000-metric-ton-per-day (t/d) open pit mine with a 27,000-t/d concentrator (Ray) and a 23,500-t/d concentrator (Hayden), a 13,600-t/d silicate leaching system, a low-grade sulfide dump leaching system, and a SX-EW operation. The Hayden oxygen flash smelter, with an annual capacity of 650,000 t/yr of concentrates, produced 191,000 t of copper anode. Asarco's El Paso smelter remained on standby throughout the year, and production at its Silver Bell Mine and SX-EW operation in Arizona declined by about 2,000 t to 18,300 t (Grupo Mexico S.A. de C.V., 2001a, p. 10-13).

In November, Asarco initiated a new mine plan at its Mission Mine Unit in Arizona. Under the plan, ore production was reduced from 56,000 t/d to 37,000 t/d, while total material mined was increased by 25%, thus increasing the stripping ratio and extending the reserve life at the mine from 14 to 22 years. The new plan was expected to boost average ore grades, increase recovery rates, and reduce unit production costs. Annual production of copper in concentrate was expected to decline by 22,000 t (ASARCO Inc., 2000b).

Montana Resources Inc. (49% owned by Asarco) suspended milling operations at its Continental Mine in Montana on June 30, citing "a dramatic escalation in power prices" as the reason for the shutdown. Stripping operations continued after the mill closed, and the company had anticipated resuming operations by yearend when it had expected utility rates to abate after the peak summer demand (Platt's Metal's Week, 2000b). At yearend, however, the mine remained closed and was not anticipated to reopen in the near term.

Despite numerous setbacks and limited interest by investment companies, Summo Minerals Corp. continued predevelopment work on its Lisbon Valley Copper Project, San Juan County, UT. The company resumed a drilling program early in the year in the Centennial SE Extension deposit and updated reserve calculations for a revised "final feasibility study," approved in September, for submission to banks for solicitation of financing. The plan design is for an open pit, heap-leach, SX-EW project producing 18,000 t/yr of cathode during a minimum 8.5-year period at anticipated cash and full operating costs of below $0.50 and $0.75 per pound of copper, respectively. Reserves were estimated at 333 Mt of ore grading an average 0.54% copper with a stripping ratio of 2.25 (Summo Minerals Corp., 2000a; 2000b).

At Kennecott Utah Copper Corp.'s Bingham Canyon Mine, production of copper increased by 5.9% to 296,000 t, and gold output rose 44% to 529,000 ounces compared with production in 1999. A 4% increase in ore milled, combined with a 4% and 44% increase, respectively, in copper and gold grades, accounted for the production growth. Copper ore grades had fallen from 0.62% copper in 1998 to 0.55% in 1999 and recovered, beginning midyear, to an annual average of 0.57% in 2000, still below the expected life-of-the-mine average. Kennecott anticipated that large-scale underground mining would extend mine life by 15 years when open pit reserves are exhausted around 2015. Refinery output increased nominally to 269,000 t with the smelter reportedly operating in excess of rated capacity (Rio Tinto plc, 2001, p. 37).

Nord Resources Corp. was seeking financing to return the Johnson Camp copper mine to full production. Nord acquired Johnson Camp in June 1999. In the first 6 months of 2000, the company incurred losses related to the planned redevelopment of the mine but operated on a close to break-even basis after that (Nord Resources Corp., 2000b). The Johnson Camp Copper Mine, 105 kilometers east of Tucson, AZ, is currently being operated on a maintenance basis. Since 1975, the mine has produced more than 68,000 t of cathode copper from open pit mining, heap leaching, and SX-EW processing of oxide ores. Although significant reserves remain, mining operations ceased in 1997. Heap leaching continues and the mine is producing 1 to 2 million pounds of copper annually. A detailed feasibility study to restart the Johnson Camp Mine demonstrated that the mine could produce 8,900 t per year of copper cathode for 11 years at an average cash cost of $0.63 per pound. Startup costs would total $13.5 million, including $7.9 million of capital investment and $5.6 million of working capital and other costs. Current reserves are placed at 3.2 Mt grading 0.417% copper (Nord Resources Corp., 2000a).

Consumption

Reported consumption of refined copper by domestic manufacturers continued its upward trend, rising by 1.6%, to 3.03 Mt. In addition to refined copper, domestic manufacturers directly consumed (melted or processed into chemicals) 1.3 Mt of copper-base scrap containing about 1 Mt of recoverable copper. An additional 75,000 t of copper was recovered in the consumption of aluminum-, nickel-, and zinc-base scrap.

Consumption of refined copper at wire-rod mills increased nominally and accounted for about 74% of domestic consumption of refined copper. For the third consecutive year, consumption growth at wire-rod mills was moderated by increased imports of wire rod, principally from Canada and Mexico, from which imports rose by 45,000 t to 225,000 t in 2000. Total imports rose by 63,000 t. Capacity utilization at domestic mills remained high following closure of two wire-rod mills in 1999. According to industry reports, despite increased imports, the U.S. wire-rod market was tight and at midyear experienced supply shortages. Wire-rod inventories in June fell to their lowest levels in recent years. An extended maintenance

Digitized by Google

shut down at Grupo Minero Mexico S.A.'s Mexican wire-rod mill led to a 20% cutback in shipments in June, and production difficulties were also reported at Southwire Co., which had closed its secondary smelter and electrolytic refinery at the end of May (Platt's Metals Week, 2000d). In response to limited U.S. capacity and expectations of continued demand growth, Alcatel, a French-owned communications company with wire-rod mills in Canada, France, and Germany, announced plans to construct a 200,000-t/yr wire-rod mill in the southeastern United States. Commissioning was anticipated in 2 to 3 years (Platt's Metals Week, 2000a).

At brass mills, which were the second largest consumers of refined copper, consumption of refined copper rose by about 5%, while consumption of copper-base scrap rose by less than 2%, reflecting the continued impact of relatively low copper prices that reduced the cost of using refined copper and reduced the availability of scrap for processing. Brass mills still remained the largest consumers of scrap, accounting for about two-thirds of the total copper recoverable from scrap.

According to data compiled by the CDA (2001, p. 18), the supply of copper and copper-alloy products to the U.S. market by fabricators (wire mills, brass mills, foundries, and powder producers), including net imports, rose by about 4% to 4.3 Mt, up from the revised total of 4.16 Mt in 1999, and contained an estimated 3.9 Mt of copper. About 71% of these shipments was as unalloyed copper products. Wire mill products accounted for about 49% of total shipments to the domestic market; brass mill products, 47%; and foundry and powder products, 4%. In building construction, the largest end-use sector, shipments were essentially unchanged and accounted for about 39% of the market, down from 41% the previous year. Building construction included products used for building wire, plumbing and heating, air conditioning and commercial refrigeration, builders hardware, and architectural applications. Shipments for electric/electronic products and consumer/general products rose by 9% and 11%, respectively, and accounted for 28% and 11% of the market, respectively. Shipments for transportation equipment, 11%, and industrial machinery, 11%, rose slightly.

In May, Cerro Copper Products Co. announced that it had broken ground on a new "flagship" tube manufacturing and distribution center in Cedar City, UT. The tube mill was expected to be commissioned in 2001. The facility is part of a 3-year, $125 million expansion program. In addition to employing a unique, Cerro-developed process to produce both plumbing and air conditioning tube, the mill will be the only tube mill in the western United States (Cerro Copper Products, 2000). According to the Copper Development Association Inc. data (2001, p. 17), though down slightly in 2000, plumbing and commercial tube shipments to the U.S. market have risen 14% since 1995.

Prices and Stocks

Despite growing global inventories, copper prices in January continued the upward trend begun in mid-1999 and rose to their highest level in almost 2 years. The Commodity Exchange (COMEX) spot price averaged $0.85 per pound in January. With global inventories held on the commodity exchanges continuing to rise in February, prices began to weaken. Despite a sharp reversal in the upward trend in global inventories beginning in March, prices remained lower, the COMEX price averaging only $0.80 per pound in the March to June period. According to data compiled by the International Copper Study Group (2001a, p. 6), monthend inventories of refined copper on the global exchanges (LME, COMEX, and Shanghai Futures Exchange) peaked in February at 990,000 t before beginning a sustained slide that lasted through November when monthend inventories fell to 495,000 t. Prices began to respond to the decline in global stocks in May, and the average monthly COMEX price climbed to $0.91 per pound in September. Prices weakened and fluctuated during the fourth quarter of the year, the COMEX price averaging $0.86 per pound and finishing the year at $0.85 per pound. At yearend, inventories of copper held on the metals exchanges totaled 530,000 t, and total reported inventories, as reported by the International Copper Study Group (ICSG), decreased to 1.31 Mt, down from 1.62 Mt in 1999. At the prevailing rate of consumption, global inventories at yearend represented only about 31 days of supply, down from 41 days in 1999.

Trade

Net imports of refined copper rose sharply for the fifth consecutive year to 962,000 t, compared with 812,000 t in 1999. General imports of refined copper (1,025,000 t) were 30,000 t lower than imports for consumption as bonded material was removed from U.S.-located London Metal Exchange Ltd. (LME) warehouses. Beginning in March, LME inventories declined steadily and at yearend totaled 204,000 t, down from 412,000 t at yearend 1999. Exports of refined copper rose to 94,000 t, up from 25,000 t in 1999, and accounted for some of the drawdown in LME inventories.

Reduced domestic capacities led to shifts in the trade pattern for several copper products. Continuing the trend begun during the second half of 1999 following the closure of three primary smelters, the United States reverted to being a net exporter of copper in concentrates during 2000. The United States exported 175,000 t of copper in concentrate while having only negligible imports. Prior to 1998, the United States had been a long-term net exporter of concentrates. Reduced secondary processing capacity led to a surge in scrap exports; combined scrap exports of 486,000 t for 2000 exceeded exports of 315,000 t in 1999. China, including Hong Kong, was the largest recipient, accounting for 223,000 t, 46%, of total scrap exports. Owing to reduced capacity at domestic wire-rod mills, growth in industrial demand for wire rod was met by increased imports. Wire-rod imports (as reported by the U.S. Census Bureau and adjusted by the U.S. Geological Survey) rose to 247,000 t, up from 197,000 t in 1999 and 108,000 t in 1998.

According to U.S. Census Bureau data compiled by the Copper and Brass Fabricators Council Inc. (2001, p. 1-9), the United States imported 394,000 t of copper and copper-alloy semifabricated products, excluding wire-rod mill products, and exported 158,000 t. Net imports rose to 236,000 t, up from 139,000 t in 1999 and 86,000 t in 1998. Canada and Mexico accounted for 75% of semifabricated copper exports and 30% of imports.

Each year during the anniversary month of the publication of an antidumping or countervailing duty order, finding, or suspension of investigation, interested parties may request that the Department of Commerce conduct a review of the prevailing ruling. Numerous copper products for which antidumping or

Digitized by Google

countervailing duties have been imposed were subject to review in 2000. In May, the International Trade Administration (ITA) ruled that revocation of antidumping duty orders against brass sheet and strip from the Republic of Korea, the Netherlands, and Sweden was not likely to lead to recurrence or continuation of material injury to the domestic industry and that it was revoking the duties effective January 1, 2000 (U.S. Department of Commerce, 2000b). Conversely, the ITA ruled to maintain antidumping and countervailing duty orders for brass sheet and strip from Brazil, Canada, France, Germany, Italy, and Japan (U.S. Department of Commerce, 2000a).

World Review

The global production oversupply for refined copper that developed at midyear 1997, and continued into 1999, began to shift during the first quarter of 2000. According to data compiled by the ICSG, reported world inventories of refined copper by the end of June had declined 220,000 t from those held at yearend 1999, and by yearend 2000 were down by 310,000 t to 1.3 Mt. At the prevailing rate of consumption, yearend world inventories represented a 31-day supply of refined copper, down from about 42 days at the end of 1999. Inventories held in LME warehouses declined by 433,000 t, overshadowing increases in reported consumer and Shanghai Futures Exchange inventories. The transition from production surplus in 1999 to production deficit in 2000 reflects a slowdown in refined production growth and an almost 8% growth in world refined copper consumption to 15.3 Mt. While consumption grew only about 2% in North America to 3.74 Mt, consumption by European Union countries grew by about 7% to 4.1 Mt, and Asian countries by about 11% to 6.1 Mt. Growth was particularly strong in China, where usage grew by about 25% to 1.88 Mt (International Copper Study Group, 2001a).

In 2000, despite the decline in U.S. capacity, estimated world mine capacity rose by 470,000 t/yr, or 3.4%, to 14.4 Mt/yr, extending the strong growth trend that began in 1995. Chile, Indonesia, and Kazakhstan accounted for most of the capacity expansion, their capacities having grown by 270,000 t/yr, 145,000 t/yr, and 90,000 t/yr, respectively. Capacity also increased significantly in Australia (33,000 t/yr) and China (30,000 t/yr). World smelter capacity, which had trended upward over the preceding 5 years, declined by about 150,000 t/yr. Indefinite closures of U.S. smelters were partially offset by expanded capacity in Australia (110,000 t/yr), where the Mount Isa smelter reached full capacity and the new Port Kembla smelter was commissioned during the year. In Korea, incremental expansions of the Onsan smelters boosted capacity by about 40,000 t/yr; in Bulgaria, expansion of the UM Pirdop smelter increased capacity by 45,000 t/yr; and in China, installation of an Isasmelt furnace at the Yunnan smelter boosted capacity by about 50,000 t (International Copper Study Group, 2001c, p.1-56). According to CRU International Ltd. (2001, p. 54-55), the supply of copper concentrates for smelting exceeded demand by about 230,000 t/yr of contained copper, and contract treatment (smelting) and refining charges assessed by smelters averaged about $0.18 per pound of recoverable copper, essentially unchanged from that in 1999.

World refinery capacity rose by about 140,000 t/yr, less than 1%, principally owing to expansion of electrowinning capacity in Chile. The decline in U.S. electrolytic refining capacity was offset by increased capacity in Australia, where the Port Kembla refinery was commissioned (60,000 t/yr expanding to 120,000 t/yr) and the Olympic Dam refinery was expanded by about 50,000 t/yr. In Indonesia, capacity increased by about 30,000 t/yr at the Gresik refinery, commissioned in 1999 (International Copper Study Group, 2000c, p. 57-98).

Outlook

U.S. mine production is expected to decline by about 100,000 t in 2001 as the full impact of 2000 mine plan changes is realized and new cost saving programs are implemented. Production is expected to decline by an additional 40,000 t in 2002. The Morenci Mine in Arizona already closed its remaining concentrator and converted to an all leach operation during the first quarter 2001, reducing its total output but increasing production of electrowon copper. At Miami, suspension of stripping in 2000 was expected to reduce output in 2001 and 2002 by 16,000 t and 38,000 t, respectively. The mine plan implemented by Asarco at its Mission Mine at yearend should further reduce production in 2001 by about 20,000 t. In June 2001, Kennecott announced that it would suspend operations from its higher cost North concentrator, reducing ore throughput by about 18% (Kennecott Utah Copper Corp., 2001). Following cutbacks in concentrate output, the three primary smelters closed in 1999 are expected to remain shuttered.

Primary refined production in 2001 is expected to decline only slightly owing to a decrease in net exports of concentrate and increased electrowon production. Secondary refined production is expected to fall following the May closure of Southwire Co.'s secondary smelter.

Domestic consumption of refined copper during the first 6 months of 2001 was down by about 10% from the same period in 2000. In addition to a more than 100,000 t decline in copper consumption at wire-rod mills, weakness in the wire-rod market was indicated by a 20,000-t decline in net imports of wire rod for the first 6 months of the year. Economic slowdown during the second half of 2001 was expected to keep demand at or below first half levels.

At the Annual General Session of the ICSG, held in June 2001, in Lisbon, Portugal, a consensus view of the world balance of copper supply and use for refined copper was developed by Government and industry delegates. According to the consensus, world production of refined copper from both primary and secondary sources in 2001 (adjusted to reflect primary feed shortages and disruptions to operations) is projected to increase by about 500,000 t (3.4%), while world refined copper use is expected to decline by about 100,000 t (less than 1%). This forecast follows a 10-year period of sustained demand growth. Consequently, the production deficit that developed in 2000 was expected to be reversed, and a small surplus of about 130,000 t of refined copper was anticipated. At the prevailing rate of use, this surplus represents only about a 3-day supply of copper. Projections by the ICSG for 2002 indicate that refined production, adjusted to reflect feed shortages and disruptions, will increase by only about 0.5% and will not keep pace with the projected 3.7% growth in demand. As a result, a production deficit is expected for 2002 (International Copper Study Group, 2001b).

TABLE 1
SALIENT COPPER STATISTICS 1/

(Metric tons unless otherwise specified)

		1996	1997	1998	1999	2000
United States:						
Mine production:						
Ore concentrated	thousand metric tons	274,000	284,000	268,000	236,000	202,000
Average yield of copper 2/	percent	0.47 r/	0.46	0.46	0.42 r/	0.44
Recoverable copper:						
Arizona		1,240,000	1,250,000	1,190,000	1,050,000	928,000
Michigan, Montana, Utah		339,000	337,000	337,000	313,000	W
New Mexico		256,000	259,000	252,000	197,000	195,000
Other States		85,600	96,500	78,900	37,400	321,000
Total		1,920,000	1,940,000	1,860,000	1,600,000	1,440,000
Total value	millions	$4,610	$4,570	$3,220	$2,680	$2,810
Smelter production:						
From domestic and foreign ores		1,300,000	1,440,000	1,490,000	1,090,000	(3/)
From scrap (new and old)		339,000	285,000	232,000	205,000	(3/)
Total		1,640,000	1,720,000	1,720,000	1,290,000	1,000,000
Byproduct sulfuric acid, sulfur content	thousand metric tons	1,240	1,430	1,420	1,130	830
Refinery production, primary materials:						
Electrolytic from domestic ores		1,290,000	1,370,000	1,290,000	1,110,000	865,000
Electrolytic from foreign materials		147,000	113,000	238,000	196,000	163,000
Electrowon		574,000	586,000	609,000	586,000	557,000
Total		2,010,000	2,070,000	2,140,000	1,890,000	1,590,000
Refinery production, secondary materials (scrap):						
Electrolytic		193,000	233,000	202,000	156,000	(3/)
Fire refined		152,000	163,000	147,000	73,700	(3/)
Total		345,000	396,000	349,000	230,000	208,000
Grand total		2,350,000	2,470,000	2,490,000	2,120,000	1,790,000
Secondary copper produced:						
Recovered from new scrap		891,000	967,000	956,000	949,000 r/	952,000
Recovered from old scrap		428,000	498,000	466,000	381,000	363,000
Total		1,320,000	1,460,000	1,420,000	1,330,000	1,310,000
Copper sulfate production		43,400	48,400	44,000 r/	52,700	55,500
Exports:						
Refined		169,000	92,900	86,200	25,200	93,600
Unmanufactured 4/		748,000	628,000	412,000	395,000	650,000
Imports:						
Refined		543,000	632,000	683,000	837,000	1,060,000
Unmanufactured 4/		961,000	999,000	1,190,000	1,280,000	1,350,000
Copper stocks, December 31:						
Blister and in-process material		173,000	180,000	160,000	138,000	122,000
Refined copper:						
Refineries		32,200	59,700	44,200	9,830	14,800
Wire rod mills		32,100	24,600	37,300	32,500 r/	28,600
Brass mills		14,000	14,300	20,800	23,800 r/	23,600
Other industry		2,700	3,390	3,870	3,870 r/	4,680
New York Commodity Exchange (COMEX)		26,600	83,000	85,200	83,100	58,700
London Metal Exchange (LME), U.S. warehouses		38,300	129,000	341,000	412,000	204,000
Total		146,000	314,000	532,000	565,000 r/	334,000
Consumption:						
Refined copper, reported		2,610,000	2,790,000	2,890,000	2,980,000 r/	3,030,000
Apparent consumption, primary refined and old scrap 5/		2,830,000	2,940,000 r/	3,030,000 r/	3,130,000	3,110,000
Price:						
Producer, weighted average	cents per pound	109.04	106.95	78.64	75.91	88.16
COMEX, first position	do.	105.87	103.58	75.08	72.11	83.97
LME, Grade A cash	do.	104.05	103.25	75.01	71.33	82.24
World, production:						
Mine	thousand metric tons	11,000	11,400	12,100 r/	12,700 r/	13,200 e/
Smelter	do.	10,800	11,200 r/	11,400	11,700 r/	11,900 e/
Refinery	do.	12,700	13,500	14,200 r/	14,600 r/	15,000 e/

e/ Estimated. r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Other States."

1/ Data are rounded to no more than three significant digits, except prices; may not add to totals shown.

2/ Yield calculations are for concentrated ore only.

3/ Withheld to avoid disclosing company proprietary data; included in "Total."

4/ Includes copper content of alloy scrap.

5/ In 1998, 1999, and 2000, apparent consumption is calculated using General imports of 725,000 tons, 915,000 tons, and 1,020,000 tons respectively.

TABLE 2
LEADING COPPER-PRODUCING MINES IN THE UNITED STATES IN 2000, IN ORDER OF OUTPUT 1/

Rank	Mine	County and State	Operator	Source of copper	Capacity (thousand metric tons)
1	Morenci	Greenlee, AZ	Phelps Dodge Corp.	Copper ore, concentrated and leached	450
2	Bingham Canyon	Salt Lake, UT	Kennecott Utah Copper Corp.	Copper-molybdenum ore, concentrated	310
3	Ray	Pinal, AZ	ASARCO Inc.	Copper ore, concentrated and leached	150
4	Chino	Grant, NM	Phelps Dodge Corp.	Copper-molybdenum ore, concentrated and leached	125
5	Bagdad	Yavapai, AZ	do.	do.	115
6	Sierrita	Pima, AZ	do.	do.	120
7	Mission Complex	do.	ASARCO Inc.	Copper ore, concentrated	110
8	Tyrone	Grant, NM	Burro Chief Copper Co.	Copper ore, leached	75
9	Miami (Inspiration)	Gila, AZ	Phelps Dodge Corp.	do.	75
10	Continental	Silver Bow, MT	Montana Resources Inc.	Copper-molybdenum ore, concentrated	50
11	Silver Bell	Pima, AZ	ASARCO Inc.	Copper ore, leached	21
12	San Manuel	Pinal, AZ	BHP Copper Co.	do.	25
13	Miami	Gila, AZ	do.	do.	12
14	Pinto Valley	do.	do.	do.	10

1/ The mines in this list accounted for 99% of the U.S. mine production in 2000.

TABLE 3
MINE PRODUCTION OF COPPER-BEARING ORES AND RECOVERABLE COPPER CONTENT OF ORES PRODUCED IN THE UNITED STATES, BY SOURCE AND TREATMENT PROCESS 1/

(Metric tons)

	1999		2000	
Source and treatment process	Gross weight	Recoverable copper	Gross weight	Recoverable copper
Mined copper ore:				
Concentrated	236,000,000	1,000,000	202,000,000 2/	879,000
Leached	NA	586,000	NA	557,000
Total	NA	1,590,000	NA	1,440,000
Copper precipitates shipped: leached from tailings, dumps, and in-place material	7,850 r/	6,230	3,910	2,810
Other copper-bearing ores 3/	6,550,000	7,220	9,880,000	5,310
Grand total	XX	1,600,000	XX	1,440,000

r/ Revised. NA Not available. XX Not applicable.
1/ Data rounded to three significant digits; may not add to totals shown.
2/ In 2000, 17,243 kilograms of gold and 285 metric tons of silver were recovered from concentrated ore. The average value of gold and silver per metric ton of ore concentrated was $0.72.
3/ Includes gold ore, lead ore, silver ore, silver-copper ore, zinc ore, and ore shipped directly to smelter.

TABLE 4
CONSUMPTION OF COPPER AND BRASS MATERIALS IN THE UNITED STATES, BY ITEM 1/

(Metric tons)

Item	Brass mills	Wire rod mills	Foundries, chemical plants, miscellaneous users	Smelters, refiners, ingot makers	Total
1999:					
Copper scrap	1,010,000 r/	W	79,900	535,000 r/ 2/	1,630,000
Refined copper 3/	691,000	2,230,000	52,200 r/	4,480	2,980,000 r/
Hardeners and master alloys	703	--	2,100	--	2,800
Brass ingots	--	--	124,000 r/	--	124,000 r/
Slab zinc	55,800	--	(4/)	(4/)	78,200 r/
2000:					
Copper scrap	1,030,000	W	83,000	482,000 2/	1,600,000
Refined copper 3/	723,000	2,240,000	59,800	4,590	3,030,000
Hardeners and master alloys	621	--	2,260	--	2,880
Brass ingots	--	--	122,000	--	122,000
Slab zinc	57,500	--	(4/)	(4/)	82,800

See footnotes at end of table.

TABLE 4--Continued
CONSUMPTION OF COPPER AND BRASS MATERIALS IN THE UNITED STATES, BY ITEM 1/

r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Smelters, refiners, ingot makers." -- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes item indicated by symbol W.
3/ Detailed information on consumption of refined copper can be found in table 5.
4/ Withheld to avoid disclosing company proprietary data; included in "Total."

TABLE 5
CONSUMPTION OF REFINED COPPER SHAPES IN THE UNITED STATES, BY CLASS OF CONSUMER 1/

(Metric tons)

Class of consumer	Cathodes	Ingots and ingot bars	Cakes and slabs	Wirebar, billets, other	Total
1999:					
Wire rod mills	2,220,000	--	--	16,800	2,230,000
Brass mills	492,000	18,300	79,300	102,000	691,000
Chemical plants	--	--	--	1,220	1,220
Ingot makers	W	W	W	4,480 2/	4,480
Foundries	3,460	6,100 r/	--	11,600	21,200 r/
Miscellaneous 3/	W	W	W	29,800 2/	29,800
Total	2,710,000	24,400 r/	79,300	166,000	2,980,000 r/
2000:					
Wire rod mills	2,220,000	--	--	18,700	2,240,000
Brass mills	501,000	18,300	101,000	103,000	723,000
Chemical plants	--	--	--	1,200	1,200
Ingot makers	W	W	W	4,590 2/	4,590
Foundries	3,810	5,530	--	16,700	26,000
Miscellaneous 3/	W	W	W	32,600 2/	32,600
Total	2,730,000	23,800	101,000	176,000	3,030,000

r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Wirebar, billets, other." -- Zero.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes items indicated by symbol W.
3/ Includes consumers of copper powder and copper shot, iron and steel plants, primary smelters producing alloys other than copper, and other manufacturers.

TABLE 6
COPPER RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES,
BY KIND OF SCRAP AND FORM OF RECOVERY 1/

(Metric tons)

	1999	2000
Kind of scrap:		
New scrap:		
Copper-base	903,000	906,000
Aluminum-base	46,200 r/	45,500
Nickel-base	94	18
Total	949,000 r/	952,000
Old scrap:		
Copper-base	349,000	334,000
Aluminum-base	31,200 r/	28,400
Nickel-base	44	170
Zinc-base	31	32
Total	381,000	363,000
Grand total	1,330,000	1,310,000
Form of recovery:		
As unalloyed copper:		
At electrolytic plants	156,000	128,000
At other plants	81,800	88,400
Total	238,000	217,000
In brass and bronze	1,000,000	1,010,000
In alloy iron and steel	599 r/	549
In aluminum alloys	78,200 r/	74,900

See footnotes at end of table.

TABLE 6--Continued
COPPER RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES,
BY KIND OF SCRAP AND FORM OF RECOVERY 1/

(Metric tons)

	1999	2000
Form of recovery--Continued:		
In chemical compounds	11,800 2/	11,700
Total	1,090,000	1,100,000
Grand total	1,330,000	1,310,000

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ 1999 data reflects expanded coverage to include copper sulfate and other copper chemical producers.

TABLE 7
COPPER RECOVERED AS REFINED COPPER AND IN ALLOYS AND OTHER FORMS
FROM COPPER-BASE SCRAP PROCESSED IN THE UNITED STATES, BY TYPE OF OPERATION 1/

(Metric tons)

	From new scrap		From old scrap		Total	
Type of operation	1999	2000	1999	2000	1999	2000
Ingot makers	34,700	29,900	94,700	90,700	129,000	121,000
Refineries 2/	48,800	39,000	181,000	169,000	230,000	208,000
Brass and wire rod mills	804,000	822,000	25,900	22,200	830,000	844,000
Foundries and manufacturers	11,400	10,800	40,000	44,500	51,400	55,400
Chemical plants 3/	3,940	3,880	7,840	7,840	11,800	11,700
Total	903,000	906,000	349,000	334,000	1,250,000	1,240,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Electrolytically refined and fire-refined scrap based on source of material at smelter level.
3/ 1999 data reflects expanded coverage to include copper sulfate and other copper chemical producers.

TABLE 8
PRODUCTION OF SECONDARY COPPER AND COPPER-ALLOY PRODUCTS
IN THE UNITED STATES, BY ITEM PRODUCED FROM SCRAP 1/

(Metric tons)

Item produced from scrap	1999	2000
Unalloyed copper products:		
Electrolytically refined copper	156,000	128,000
Fire-refined copper	73,700	80,000
Copper powder	7,420	7,510
Copper castings	647	839
Total	238,000	217,000
Alloyed copper products:		
Brass and bronze ingots:		
Tin bronzes	15,800 r/	14,600
Leaded red brass and semired brass	97,300 r/	93,500
High leaded tin bronze	13,000	12,700
Yellow brass	6,010	5,650
Manganese bronze	7,060 r/	6,240
Aluminum bronze	6,870	7,030
Nickel silver	2,050	2,260
Silicon bronze and brass	4,530	4,680
Copper-base hardeners and master alloys	13,200 r/	13,800
Miscellaneous	169 r/	3,500
Total	166,000 r/	164,000
Brass mill and wire-rod mill products	1,030,000	1,060,000
Brass and bronze castings	43,400	45,600
Brass powder	214	198
Copper in chemical products	11,800 2/	11,700
Grand total	1,490,000 r/	1,490,000

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ 1999 data reflects expanded coverage to include copper sulfate and other copper chemical products.

TABLE 9
COMPOSITION OF SECONDARY COPPER-ALLOY PRODUCTION IN THE UNITED STATES 1/

(Metric tons)

	Copper	Tin	Lead	Zinc	Nickel	Aluminum	Total
Brass and bronze ingot production: 2/							
1999 r/	137,000	4,850	7,900	15,700	267	19	166,000
2000	136,000	5,240	8,430	14,400	252	14	164,000
Secondary metal content of brass mill products:							
1999	830,000	950	7,840	188,000	W	W	1,030,000
2000	844,000	1,650	7,450	199,000	W	W	1,060,000
Secondary metal content of brass and bronze castings:							
1999	39,100	708	1,100	2,260	112	119	43,400
2000	42,200	633	837	1,700	85	98	45,600

r/ Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Includes about 97% from scrap and 3% from other than scrap in 1999 (revised) and about 96% from scrap and 4% from other than scrap in 2000.

TABLE 10
CONSUMPTION AND YEAREND STOCKS OF COPPER-BASE SCRAP 1/

(Metric tons, gross weight)

	1999		2000	
Scrap type and processor	Consumption	Stocks	Consumption	Stocks
No. 1 wire and heavy:				
Smelters, refiners, ingot makers	106,000	2,360 r/	86,000	2,260
Brass and wire-rod mills	431,000	(2/)	438,000	(2/)
Foundries and miscellaneous manufacturers	41,200	2,520	45,500	2,650
No. 2 mixed heavy and light:				
Smelters, refiners, ingot makers	137,000	6,020 r/	133,000	2,120
Brass and wire-rod mills	21,200	(2/)	13,800	(2/)
Foundries and miscellaneous manufacturers	3,230	226	3,320	193
Total unalloyed scrap:				
Smelters, refiners, ingot makers	243,000	8,380 r/	219,000	4,370
Brass and wire-rod mills	452,000	20,300	452,000	17,600
Foundries and miscellaneous manufacturers	44,500	2,740 r/	48,800	2,840
Red brass: 3/				
Smelters, refiners, ingot makers	50,200	2,150 r/	52,700	2,120
Brass mills	10,400	(2/)	9,330	(2/)
Foundries and miscellaneous manufacturers	10,600	(2/)	12,400	(2/)
Leaded yellow brass:				
Smelters, refiners, ingot makers	20,600	1,110 r/	16,500	1,210
Brass mills	400,000	(2/)	396,000	(2/)
Foundries and miscellaneous manufacturers	1,740	(2/)	1,680	(2/)
Yellow and low brass, all plants	76,600	1,160 r/	105,000	713
Cartridge cases and brass, all plants	79,400	(2/)	72,600	(2/)
Auto radiators:				
Smelters, refiners, ingot makers	53,400	2,130 r/	48,300	1,610
Foundries and miscellaneous manufacturers	4,650	(2/)	2,750	(2/)
Bronzes:				
Smelters, refiners ingot makers	16,100	886 r/	11,100	1,130
Brass mills and miscellaneous manufacturers	10,600	(2/)	11,800	(2/)
Nickel-copper alloys, all plants	23,000	369 r/	28,100	314
Low grade and residues:				
Smelters, refiners, miscellaneous manufacturers	111,000	13,100 r/	88,600	7,670
Other alloy scrap: 4/				
Smelters, refiners, ingot makers	12,100	839 r/	11,300	324
Brass mills and miscellaneous manufacturers	6,740	(2/)	7,600	(2/)
Total alloyed scrap:				
Smelters, refiners, ingot makers	258,000	21,200 r/	221,000	15,300
Brass mills	593,000	35,500	620,000	39,500
Foundries and miscellaneous manufacturers	35,500	3,030 r/	34,200	2,360
Total scrap:				
Smelters, refiners, ingot makers	501,000	29,600 r/	440,000	19,600
Brass and wire-rod mills	1,050,000	55,700	1,070,000	57,200
Foundries and miscellaneous manufacturers	79,900	5,770 r/	83,000	5,210

TABLE 10--Continued
CONSUMPTION AND YEAREND STOCKS OF COPPER-BASE SCRAP 1/

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Individual breakdown is not available; included in "Total unalloyed scrap," "Total alloyed scrap," and "Total scrap."
3/ Includes cocks and faucets, commercial bronze, composition turnings, gilding metal, railroad car boxes, and silicon bronze.
4/ Includes aluminum bronze, beryllium copper, and refinery brass.

TABLE 11
CONSUMPTION OF PURCHASED COPPER-BASE SCRAP 1/ 2/

(Metric tons, gross weight)

Type of operation	From new scrap		From old scrap		Total	
	1999	2000	1999	2000	1999	2000
Ingot makers	46,300	44,000	132,000	125,000	178,000	169,000
Smelters and refineries	71,100	58,800	252,000	212,000	323,000	271,000
Brass and wire-rod mills	1,020,000	1,050,000	26,800	23,000	1,050,000	1,070,000
Foundries and miscellaneous manufacturers	27,200	26,200	52,700	56,800	79,900	83,000
Total	1,160,000	1,180,000	464,000	417,000	1,630,000	1,600,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Consumption at brass and wire-rod mills assumed equal to receipts.

TABLE 12
FOUNDRIES AND MISCELLANEOUS MANUFACTURERS
CONSUMPTION OF BRASS INGOT, REFINED COPPER AND
COPPER SCRAP IN THE UNITED STATES 1/

(Metric tons)

Ingot type or material consumed	1999	2000
Tin bronzes	33,200	29,900
Leaded red brass and semired brass	70,100 r/	71,000
Yellow, leaded, low brass 2/	8,520 r/	8,510
Manganese bronze	4,720	4,590
Nickel silver 3/	2,710	3,480
Aluminum bronze	4,140	4,650
Hardeners and master alloys 4/	2,100	2,260
Lead free alloys 5/	141 r/	145
Total brass ingot	126,000 r/	125,000
Refined copper	52,200 r/	59,800
Copper scrap	79,900	83,000

r/ Revised.
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes brass and silicon bronze.
3/ Includes brass, copper nickel, and nickel bronze.
4/ Includes special alloys.
5/ Includes copper-bismuth and copper-bismuth-selenium alloys.

TABLE 13
AVERAGE PRICES FOR COPPER SCRAP AND ALLOY-INGOT, BY TYPE

(Cents per pound)

Year	Brass mills No. 1 scrap	Refiners No. 2 scrap	Dealers' buying (New York) No. 2 scrap	Dealers' buying (New York) Red brass turnings and borings	Alloy-ingot (New York) 1/ No. 115 brass (85-5-5-5)	Alloy-ingot (New York) 1/ Yellow brass (405)
1999	70.88	57.53	42.97	37.74	138.50	135.25
2000	80.67	64.99	51.43	39.95	138.50	135.25

r/ Revised. -- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Total imports of wire rod in 1999 were 193,000 tons valued at $330,000,000 and in 2000 were 247,000 tons valued at $502,000,000. Imports data adjusted by USGS to correct misclassification of imports from Mexico.

3/ C.i.f. value at U.S. port.

4/ Less than 1/2 unit.

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through July 20, 2001.

3/ Reported figure.

4/ Copper content of pelletized nickel-copper matte produced in smelter.

5/ Reported by Comision Chilena del Cobre. Includes recoverable copper content of nonduplicative mine and metal products produced from domestic ores and concentrates and leach production for electrowinning.

6/ Recoverable content.

7/ Less than 1/2 unit.

8/ Excludes copper content of pyrite.

9/ Data are for fiscal years beginning April 1 of year stated. Zambian-mined copper reported recovered during smelting and electrowinning.

e/ Estimated. r/ Revised. W Withheld to avoid disclosing company proprietary data; included in total. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through July 20, 2001.

3/ Reported figure.

4/ Copper content of nickel-copper matte exported to Norway for refining.

5/ Data are for year beginning March 21 of year stated. Secondary production is estimated to be about 5% of total.

6/ Secondary production is estimated to be about 5% to 10% of total.

7/ For fiscal year beginning April 1 of year stated. Electrowon is total electrowon production reported less the quantity reported as "finished production, leach cathodes."

8/ Includes impure cathodes produced by electrowinning in nickel processing.

9/ U.S. production undifferentiated in 2000.

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through July 20, 2001.

3/ Reported figure.

4/ Includes reprocessed leach cathode from Congo (Kinshasa).

5/ Excludes leach cathode exported for processing in Belgium.

6/ Data are for Iranian years beginning March 21 of that stated.

7/ May include secondary.

8/ Data are for fiscal year beginning April 1 of that stated. Electrowon covers only presumably high-grade electrowon cathodes reported as "finished production leach cathodes." Other, in addition to electrowon cathodes, includes a smaller amount of "finished product shapes" presumably cast from electro-refined cathodes, or any blister-anodes and low-anodes and low-grade electrowon cathodes that were furnace- or fire-refined.

DIAMOND, INDUSTRIAL

By Donald W. Olson

Domestic survey data and tables were prepared by Christine K. Pisut, statistical assistant, and the world production tables were prepared by Regina R. Coleman, international data coordinator.

Diamond is best known for its gem qualities, but some of its unique properties make it ideal for many industrial and research applications as well. Current information on gem-grade diamond can be found in the U.S. Geological Survey minerals yearbook chapter on gemstones. Diamond is the hardest known material and has the highest thermal conductivity of any material at room temperature (May, 1995). Diamond is more than twice as hard as cubic boron nitride or silicon nitride, which are the nearest competitors (Ravi, 1994, p. 537). Because it is the hardest substance known, diamond has been used for centuries as an abrasive in grinding, drilling, cutting, and polishing, and industrial-grade diamond continues to be used as an abrasive for many applications. Diamond that does not meet gem-quality standards for clarity, color, shape, or size is used as industrial-grade diamond. Even though it has higher unit cost, diamond has proven to be more cost effective in many industrial processes because it cuts faster and lasts longer than its rival abrasive materials (Boucher, 1997, p. 26.6). Diamond also has chemical, electrical, optical, and thermal characteristics that make it the best material available to industry for wear- and corrosion-resistant coatings, special lenses, heat sinks in electrical circuits, wire drawing, and advanced technologies.

Both synthetic and natural diamonds have industrial uses, but synthetic industrial diamond is superior to its natural counterpart because it can be produced in large quantities. In many cases, its properties can be tailored to specific applications (Boucher, 1996). It is for these reasons that manufactured diamond accounts for more than 90% of the industrial diamond used in the United States and the world.

Legislation and Government Programs

Congress has authorized the sale of all the diamonds in the National Defense Stockpile (NDS), which is managed by the Department of Defense (DOD). The NDS 2000 annual plan allowed for the sale of a portion of the stockpiled diamond stones. During 2000, the Defense National Stockpile Center (DNSC) sold 989,140 carats of diamond stone (valued at $33.44 million). At yearend 2000, the DNSC reported an NDS remaining inventory of about 1.508 million carats of industrial diamond stone valued at $15.08 million (Defense National Stockpile Center, 2000a, 2000b). The DOD plans to conduct additional future sales until all NDS diamond stone stocks are exhausted. Further NDS information is available in the "Prices" section of this report.

Production

The U.S. Geological Survey conducts an annual survey of domestic industrial diamond producers and U.S. firms that recover diamond wastes. Although most of these companies responded to the 2000 survey, a few significant firms withheld certain data that they deemed confidential. Thus, only estimates of U.S. primary and secondary output are provided in this review.

Industrial Diamond in the 20th Century

The utilitarian role of diamond was confined to lapidary products until industrialization created the first demand for diamond as an industrial tool for precision cutting and as abrasive material set in saw blades and drill bits. Few statistical data are available on abrasive diamond prior to 1911, when the United States imported $110,434 in diamond dust and bort, primarily from South Africa. After World War I, with the development of cemented carbide cutting tools, diamond was found to be the most effective medium for finishing and grinding the new ultrahard metal. This discovery rapidly increased the demand for industrial diamond. There was almost no U.S. diamond production until the early 1930s, when a relatively small diamond deposit near Murfreesboro, AR, was developed. By 1937, about two-thirds, by weight, of all diamond sold each year was used for abrasive purposes, and U.S. imports of abrasive diamond, primarily from South Africa and Brazil, were valued at just under $7 million. World War II, with its increased use of hard-metal tools in the munitions industry, further increased the demand for industrial diamond.

In 2000, synthetic diamond accounted for more than 90% of the industrial diamond market. The United States was the world's largest market for industrial diamond, as well as the largest producer of synthetic industrial diamond, with estimated production of 248 million carats. In 2000, U.S. imports of an estimated 293 million carats of industrial diamond stone, bort, grit, dust, and powder, primarily from Belgium, Ireland, Switzerland, and the United Kingdom, were valued at about $125 million. In 1955, General Electric Co. announced that its laboratories had succeeded in manufacturing synthetic diamond from carbonaceous material. Economic commercial production of synthetic industrial diamond was achieved by the early 1960s. The manufacture and use of synthetic diamond steadily increased. By the end of the 1960s, domestic production of synthetic industrial diamond had increased to 13 million carats per year, and by the early 1980s, production had reached 57 million carats per year. In 2000, synthetic industrial diamond could be made in a relatively short time, and its performance in specific end-use applications exceeded that of natural diamond.

Digitized by Google

As one of the world's leading producers of synthetic industrial diamond, the United States accounted for an estimated output of 248 million carats in 2000. Only two U.S. companies produced synthetic industrial diamond during the year—Mypodiamond, Inc., Gibbstown, NJ, and GE Superabrasives, Worthington, OH. General Electric Co., Fairfield, CT, which owns GE Superabrasives and other diamond manufacturing plants abroad, is one of the world's largest producers of industrial diamond.

In 2000, nine firms also manufactured polycrystalline diamond (PCD) from synthetic diamond grit and powder. These companies were the Dennis Tool Co., Houston, TX; GE Superabrasives, Worthington, OH; Novatek Inc., Provo, UT; Phoenix Crystal Corp., Ann Arbor, MI; Precorp Inc., Provo, UT; SII Megadiamond Industries Inc., Provo, UT; Tempo Technology Corp., Somerset, NJ; U.S. Synthetic Corp., Orem, UT; and Western Diamond Products, Salt Lake City, UT.

It is estimated that more than 10.1 million carats of used industrial diamond were recycled in the United States during 2000. Most of this material was recovered by recycling firms from used diamond drill bits, diamond tools, and other diamond-containing wastes. Additional diamond was recovered during the year from residues generated in the manufacture of PCD; most of this material was recovered for PCD from within the production operations of the PCD producing companies (Wilson Born, National Research Company, oral commun., 2001).

The recovery and sale of industrial diamond was the principal business of four U.S. companies in 2000: Industrial Diamond Laboratory Inc., Bronx, NY; Industrial Diamond Powders Co., Pittsburgh, PA; International Diamond Services Inc., Houston, TX; and National Research Company, Fraser, MI. In addition to these companies, other domestic firms may have recovered industrial diamond in smaller secondary operations.

Consumption

The United States remained the world's largest market for industrial diamond in 2000. Based on production estimates and trade data, the apparent U.S. consumption of industrial diamond during the year increased to an estimated 484 million carats, which was a record high. This growth primarily reflects expanded output in many domestic industries where diamond is used. The major consuming industries of industrial diamond in the United States during 2000 were construction, machinery manufacturing, mining services (drilling), stone cutting/polishing, and transportation systems (infrastructure and vehicles). Within these sectors, stone cutting and highway building/repair together made up the largest demand for industrial diamond. The manufacture of every automobile made in the United States consumes 1.5 carats of industrial diamond. Research and high technology uses included close-tolerance machining of ceramic parts for the aerospace industry, heat sinks for electronic circuits, lenses for laser radiation equipment, and polishing silicon wafers and disk drives in the computer industry (Bailey and Bex, 1995).

Diamond tools have myriad industrial functions. Diamond drilling bits and reaming shells are used principally for gas, mineral, and oil exploration. Other applications of diamond bits and reaming shells include foundation testing, masonry drilling, and inspecting concrete in various structures. The primary uses of point diamond tools are for dressing and truing grinding wheels and for cutting, machining, boring, and finishing; beveling glass for automobile windows is another application. Cutting dimension stone and cutting/grooving concrete in highway reconditioning are the major uses of diamond saws; other applications include cutting composites and forming refractory shapes for furnace linings. Very fine diamond saws are used to slice brittle metals and crystals into thin wafers for electronic and electrical devices. Diamond wire dies are essential for high-speed drawing of fine wire, especially from hard, high-strength metals and alloys. The primary uses of diamond grinding wheels include edging plate glass, grinding dies, grinding parts for optical instruments, and sharpening and shaping carbide machine tool tips.

Two types of natural diamond are used by industry: diamond stone (generally larger than 60 mesh/800 microns) and diamond bort (smaller, fragmented material). Diamond stone is employed primarily in drilling bits and reaming shells used by mining companies; it also is incorporated in single- or multiple-point diamond tools, diamond saws, diamond wheels, and diamond wire dies. Diamond bort is used for drilling bits and as a loose grain abrasive for polishing. Other tools that incorporate natural diamond include engraving points, glass cutters, bearings, and surgical instruments.

Synthetic diamond grit and powder are used in diamond grinding wheels, saws, impregnated bits and tools, and as loose abrasive compounds for polishing. Diamond grinding wheels can be as much as 1 meter in diameter.

Loose powders and compounds made of synthetic diamond for polishing are used primarily to finish optical surfaces, jewel bearings, gemstones, wiredrawing dies, cutting tools, and silicon wafers for computer chips. Hundreds of other products made from metals, ceramics, plastics, and glass also are finished with diamond powders and compounds.

The use of polycrystalline diamond shapes (PDS) and polycrystalline diamond compacts (PDC) continues to increase for many of the applications cited above, including some of those that employ natural diamond. The use of PDS, PDC, and matrix-set synthetic diamond grit for drilling bits and reaming shells has increased in recent years. PDS and PDC are used in the manufacture of single- and multiple-point tools, and PDC is used in a majority of the diamond wire-drawing dies.

Prices

Natural and synthetic industrial diamonds differ significantly in price (Boucher, 1997, p. 26.6). Natural industrial diamond normally has a more limited range of values. Its price varies from about $0.45 per carat for bort-size material to about $7 to $25 per carat for most stone. Synthetic industrial diamond has a much larger range of prices than natural diamond. Prices of synthetic diamond vary according to size, shape, crystallinity, and the absence or presence of metal coatings. In general, synthetic diamond prices for grinding and polishing range from as low as $0.10 per carat to $0.95 per carat. Strong and blocky material for sawing and drilling sells for $1.50 to $4.75 per carat. Large synthetic crystals with excellent structure for specific applications sell for several hundred dollars per carat.

In 2000, the DNSC had awarded bids that ranged from $1.44 to $151.00 per carat for NDS diamond stone sold, with the average awarded bid being $33.80 per carat (Defense National Stockpile Center, 2000a, b).

Foreign Trade

The United States continued to lead the world in industrial diamond trade during 2000; imports came from 36 countries (tables 1, 2), and exports/reexports went to 55 countries (tables 3, 4). Although the United States has been a major producer of synthetic diamond for decades, its growing domestic markets have become more reliant on foreign sources of industrial diamond in recent years. U.S. markets for natural industrial diamond always have been dependent on imports and secondary recovery operations, because domestic production of natural diamond was unable to meet demand.

During 2000, U.S. imports of industrial quality diamond stones (natural and synthetic) decreased by 20% from 1999 imports to 2.52 million carats valued at $13.4 million (table 1). Imports of diamond powder, dust, and grit (natural and synthetic) increased by 39% from 1999 imports to 291 million carats valued at $111 million (table 2).

During 2000, U.S. exports and reexports of industrial diamond stone decreased by approximately 9% from 1999 exports and reexports to 3.62 million carats valued at $34.6 million (table 3). Additionally, U.S. exports and reexports of industrial diamond powder, dust, and grit decreased slightly from 1999 exports and reexports to 100 million carats valued at $71.8 million (table 4). Reexports can account for a significant portion of total exports/reexports; therefore, exports and reexports are listed separately in tables 3 and 4 so that U.S. trade and consumption can be calculated more accurately.

World Review

Total industrial diamond output worldwide during 2000 was estimated to be well above 800 million carats; analyst reports estimated that global output, which was valued between $600 million and $1 billion, was at least 600 million carats (Norman Rohr, Warren Diamond Powder Co., Inc., oral commun., 1999; Wilson Born, National Research Company, oral commun., 2000). World demand for industrial diamond in the 1990s had been growing at rates of more than 10% per year (Boucher, 1997, p. 26.6).

Industrial diamond was produced in 30 countries during 2000 (tables 5, 6). In addition to the countries listed in table 6, Germany and the Republic of Korea produced synthetic diamond (Norman Rohr, Warren Diamond Powder Co., Inc., oral commun., 1999), but specific data on their output could not be confirmed. China may have produced much more than the output shown in the table (Owers, 2000; Wilson Born, National Research Company, oral commun., 2001).

In 2000, approximately 70% of the total global natural and synthetic industrial diamond output was produced in Ireland, Russia, and the United States. The dominance of synthetic diamond was even more pronounced, accounting for more than 90% of global production and consumption.

The Ekati Mine, Canada's first commercial diamond mine, completed its second full year of production. The Ekati Mine, located in the Northwest Territories, was a joint venture between BHP Diamonds Inc. (BHP) and Dia Met Minerals Ltd., but in June 2001, BHP purchased Dia Met Minerals Ltd. (BHP Diamonds Inc., 2001). Ekati has estimated reserves of 60.3 million metric tons (Mt) of ore in kimberlite pipes, containing 54.3 million carats of diamonds, and the mine life is projected to be 25 years. In 2000, Ekati produced 2.63 million carats (Luc Rombouts, Terraconsult bvba, May 2, 2001, Diamond annual review—2000, accessed June 19, 2001, at URL http://www.terraconsult.be/overview.htm). Approximately one-third of the Ekati diamond production is industrial-grade material (Darren Dyck, Senior Project Geologist, BHP Diamonds Inc., oral commun., May 27, 2001).

Two other Canadian commercial diamond mines located in the Northwest Territories are expected to commence diamond production in the first half of 2003. They are the Diavik diamonds project and the Snap Lake diamond project. Diavik has estimated reserves of 25.6 Mt of ore in kimberlite pipes, containing 102 million carats of diamonds, and the mine life is projected to be 20 years. Diavik is expected to produce about 102 million carats of diamond at a rate of 6 million carats per year worth about $63 per carat (Diavik Diamond Mines Inc., 2000, p. 10-12). The Snap Lake diamond project was acquired by De Beers Canada Mining Inc. from Winspear Diamonds Inc. and Aber Diamond Corporation in 2000. Snap Lake will be De Beers' first mine outside of southern Africa and the first underground diamond mine in Canada. Snap Lake has estimated reserves of 22.8 Mt of ore in a kimberlite dike, containing 38.8 million carats of diamonds, and the mine life is projected to be 20 years or more (De Beers Canada Mining Inc., 2000, Snap Lake diamond project fact sheet, accessed June 13, 2001, at URL http://www.debeerscanada.com/files_new/snap/infrastruct.html).

Diamond exploration is continuing in Canada, and many new deposits are being found. There have been additional discoveries in both the core and buffer zones of the Ekati lease. At least 35 kimberlites have been discovered in north-central Alberta, and 70 large kimberlites have been found in Saskatchewan. Additional discoveries have been made in Ontario and Quebec (Luc Rombouts, Terraconsult bvba, May 2, 2001, Diamond annual review—2000, accessed June 19, 2001, at URL http://www.terraconsult.be/overview.htm). When the Diavik and Snap Lake mines begin production, Canada will be producing at least 15% to 20% of the total world natural diamond production. This will make Canada a significant producer of natural industrial diamond, as well as of gem-quality diamond.

Outlook

The United States will continue to be the world's largest market for industrial diamond well into the next decade, and it will remain a significant producer and exporter of industrial diamond.

The strength of U.S. demand will depend on the vitality of the Nation's industrial base and on how well the life cycle cost effectiveness of diamond compares with competing materials that initially are less expensive. The many advantages that diamond offers for precision machining and longer tool life, which compensate for increases in other production line costs, seem certain to spur demand for diamond tools. In fact, even the use of wear-resistant diamond coatings to increase the life of materials that compete with diamond promises to be a rapidly growing application (May, 1995). Increased tool life not only leads to lower costs per unit of output but also means fewer tool changes and longer unattended production runs (Advanced Materials & Processes, 1998). In view of the many advantages that come from increased tool life and reports that diamond film surfaces can increase durability by a factor of 50 (Advanced Materials & Processes, 1998), much wider use of diamond as an

Digitized by Google

engineering material is expected.

The most dramatic increase in U.S. demand for industrial diamond is likely to occur in the construction sector as the $200 billion Transportation Equity Act for the 21st Century (Public Law 105-178, enacted June 9, 1998) is further implemented. The act provides funding for building and repair of the Nation's highway system through 2003. Demand for saw-grade diamond alone is expected to increase by more than $1 billion during the coming year to fulfill goals mandated by the act for the repair and replacement of roads, bridges, and other components in the transportation infrastructure of the country (Wilson Born, National Research Company, oral commun., 2001).

According to industry sources, PCD for abrasive tools and wear parts will continue to replace competing materials in many industrial applications by providing closer tolerances, as well as extending tool life. For example, PDC and PDS will continue to displace natural diamond stone and tungsten carbide products used in the drilling and tooling industries (Wilson Born, National Research Company, written commun., 1998).

Truing and dressing applications will remain a major domestic end use for natural industrial diamond stone. The stone cannot be manufactured commercially. No shortage of the stone is anticipated, however, because new mines and more producers selling in the rough diamond market will maintain ample supplies. More competition introduced by the additional sources also may temper price increases.

World demand for industrial diamond will continue to increase during the next few years. Constant-dollar prices of synthetic diamond products, including chemical-vapor-deposition diamond films, will decline as production technologies become more cost-effective and competition increases from low-cost producers in China and Russia.

DIATOMITE

By Thomas P. Dolley

Domestic survey data and tables were prepared by Shantae F. Hawkins, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

Production of diatomite in the United States decreased by about 9% to 677,000 metric tons (t), and its value decreased by about 3% to $173 million free on board (f.o.b.) plant in 2000, compared with 747,000 t valued at $178 million f.o.b. plant in 1999 (table 1). U.S. production of diatomite in 2000 was the lowest since 1994. The decline in production of diatomite can be attributed in part to the decline of growth of the economy and increased energy costs in late 2000 and early 2001. Mining operations that include energy costs associated with calcining, such as diatomite, were affected, particularly in California (Industrial Minerals, 2001). Despite the production decrease, the United States remained the world's largest producer and consumer of diatomite. Used primarily for filtration, major diatomite products were sold as various grades of calcined powders (table 2).

Description and Terminology

Diatomite is a chalk-like, soft, friable, earthy, very fine-grained, siliceous sedimentary rock, usually light in color (white if pure, commonly buff to gray in situ, and rarely black). It is very finely porous, very low in density (floating on water at least until saturated), and essentially chemically inert in most liquids and gases. It also has low thermal conductivity and a rather high fusion point. Diatomaceous earth (often abbreviated as D.E.) is a common alternate name but more appropriate for the unconsolidated or less lithified sediment. The deposits result from an accumulation in oceans or fresh waters of the amorphous hydrous silica (opal, $SiO_2.nH_2O$) cell walls of dead diatoms, which are microscopic single-cell, often colonial aquatic plants (algae). The diatom cells contain an internal, elaborate siliceous skeleton consisting of two valves (frustules), which fit together much like a pill box. The diatom's fossilized skeletal remains vary in size from less than 1 micrometer to more than 1 millimeter but are typically 10 to 200 micrometers across and have a broad variety of delicate, lacy, perforated shapes from spheres and cylinders to discs, ladders, feathers, and needles. Each deposit has characteristic assemblages that have been used to identify the source of material for forensic purposes. There are more than 10,000 species of extinct and living diatoms, some of which live in ice or hot springs as well as marshes or even on moist bark, but they are most abundant in sunlit water—fresh or salt—constantly enriched with suitable nutrients and dissolved silica. Live cells are covered by a jelly, and masses appear as brownish water or films on-stream bottoms. Extensive blooms of diatoms (algae) in coastal waters have caused severe pollution and anoxic conditions, and some species produce domoic acid, a nerve poison that, if ingested, quickly causes death to many animals (Eureka, November 12, 1998, Diatoms—Nature's marbles, accessed May 4, 2000, at URL http://hjs.geol.uib.no/diatoms).

Diatomite is also known as kieselgur (a German name compounded from the words for flint and for an earthy sediment in water) and as tripolite after a diatomite occurrence near Tripoli, Libya. Tripolite is used in some government trade documents as the short name for a longer description of "siliceous fossil meals and similar siliceous earths...;" the short name is used more generally in the various tariff codes that cover diatomite (U.S. International Trade Commission, January 25, 2001, Harmonized Tariff Schedule of the United States—Section V—Chapter 25, accessed June 13, 2001, at URL http://dataweb.usitc.gov/scripts/tariff/0101c25.pdf). An impure (up to 30% clay) Danish variety of diatomite is called moler.

Analysis of oven-dried samples of crude ore from many commercial operations typically shows 80% to 90% (in some

Diatomite in the 20th Century

By 1900, diatomite already had a variety of uses such as in building materials, polishing compounds, filtration, filler material in rubber, paint, roofing, and paper—a prelude to its worldwide use in the 20th century. The first discovery of diatomite in North America was made by J.W. Bailey in 1839 near West Point, NY. Alfred Nobel's invention of dynamite in 1867 resulted in the development of the world's first significant diatomite industry, as diatomite was used as an absorbent and stabilizer for dynamite and nitroglycerine. Dynamite and nitroglycerine explosives required significant amounts of diatomite and operations began to flourish. In 1900, the first U.S. patent was issued for the use of diatomite in beer filtration, which is one of diatomite's primary applications in modern times. Production of diatomite in the United States for 1900 was about 3,280 metric tons. The development of processing techniques during the 1920s (such as calcination, flux calcination, grade and sizing technologies) enabled diatomite to be used in a variety of market applications and end uses.

In 2000, the United States was the world's largest producer and consumer of diatomite, producing 677,000 tons, which accounted for about 36% of global production. Western States were the primary source of U.S. production of diatomite, the largest amount coming from the diatomite deposits of Lompoc, CA. Major diatomite products were sold as various grades of calcined powders. Diatomite continued to be used primarily for filtration (beer, cooking oils, wine), while other major uses were as absorbents, filler applications, insulation, and in cement manufacturing. China was the United States' main production competitor.

Digitized by Google

cases 95%) silica (SiO_2) plus alumina (2% to 4%, attributed mostly to clay minerals) and hematite (0.5% to 2%), with an analytical ignition loss of 4% to 6%. Apparent oven-dry block density is 320 to 640 grams per liter (g/L) (compared to 1,000 g/L for water) with 80% to 90% voids. In-place ore contains from 10% to as much as 65% water (2% to 10% in the opaline structure). Dry crude rock can absorb from 1.5 to more than 3 times its weight in water. Dry powdered natural rock has an apparent density of 80 to 250 g/L. The melting point of diatomite ranges from 1,000° C to 1,750° C (Durham, 1973; Breese, 1994).

World reserves are estimated to be 800 million metric tons (Mt), which is 400 times the current estimated annual world production of 2 Mt (table 5). Of the 800 Mt, 250 Mt are in the United States (Antonides, 1999). The world reserve base was estimated by the U.S. Bureau of Mines in 1985 to be almost 2 billion tons (Meisinger, 1985). A resource estimate based just on the dimensions of the deposits near Lompoc, CA, suggests that collectively they could meet the world's current needs for centuries. Data on reserves, however, which are defined as being currently economic using proven practices among other qualifications (U.S. Bureau of Mines and U.S. Geological Survey, 1980), are not readily available and are difficult to calculate because, in addition to considerable variation in physical and chemical properties between and even within deposits, the particular potential use and proximity to a market are major considerations.

Commercial deposits worldwide are reported as mostly freshwater lake (lacustrine) deposits of Miocene to Pleistocene age, formed between 24 million to 10 thousand years ago. The reputed world's largest producing deposit that outcrops near Lompoc is a huge marine deposit of Miocene age. Although known marine occurrences generally appear to be larger than the lacustrine deposits, a very large diatomite deposit reported in China appears to be lacustrine (Lu, 1998, p. 53). The oldest marine occurrences are believed to be of Cretaceous age, about 138 million to 66 million years ago; any older occurrences would presumably have been changed into other forms of silica. The oldest lacustrine deposits are believed to be 55 million to 38 million years old, of Eocene age. Many deposits worldwide, especially of the older marine type, have been found in uplifted coastal areas exposed to some volcanic effects (such as the Pacific Rim from Chile to Japan). Lacustrine deposits, especially in mountainous localities, also often show some association with volcanic activity (such as the Pacific Northwest). However, there are lacustrine environments where diatomite deposits are presently forming in lowlands far removed from volcanic activity (such as Florida).

Production

Recovery of diatomite from most deposits is by low-cost open pit mining because many occurrences are at or near the surface and the topography allows for open pit mining. To remove overburden and excavate ore, different combinations of rippers, dozers, scrapers, front-end loaders, power shovels, and dump trucks are used. Outside the United States, however, underground mining is fairly common (such as in Chile, China, and France) owing to deposit form and depth and topographic and other constraints. Usually, room and pillar methods are used, often with equipment similar to that used in open pits, but the smallest mines are excavated with hand tools. Explosives are not normally needed at surface or underground mines because of the rock's soft, friable nature. In Iceland, dredging is used to recover diatomaceous mud from the bottom of a lake. As climate permits, at many mines the ore is stockpiled in the open to segregate it by grade and to reduce the normally high moisture content before delivering it to the processing facility.

Diatomite processing is usually done near the mine to reduce the cost of hauling up to 65% water, but the cost of delivering energy (electric power and fuel) to the site is an offsetting consideration. Processing typically involves a series of crushing, drying, size reduction, and calcining operations, using heated air for conveying and classifying within the plant. Commonly, spiked rolls and hammer mills are used for primary crushing to a size of -1.25 centimeters (0.5 inches), while limiting damage to the diatomite structure. With the heated air and multiple passes through special "milling" fans and air cyclones, further drying, size reduction, and classifying are accomplished. The cyclones not only classify for size but also remove undesirable components in the raw feed based on density differences. Size reduction aims at separating individual frustules without destroying their delicate structure. Fines, especially from baghouses used to remove particulates from the cyclone discharge waste or recycle air, are used mostly for filler grade products, and the coarser bottom discharge particles are used for filter grades. In the latter stages of processing, calcining is normally done in rotary kilns to effect the physical and chemical changes previously mentioned. Plant operators take special precautions to overcome any free crystalline silica health hazards, particularly to the lungs, by containing dust within enclosures and requiring employees to use respirators. Although the generally high moisture in the ore reduces the free crystalline silica health hazards in mining areas, precautions are still taken.

Production cost allocations were reported for the United States in 1983 as 10% mining, 60% processing, and 30% packing and shipping; a 1990 report stated energy costs were 25% to 30% of direct costs (Breese, 1994, p. 405). The proportion of the product that is calcined directly affects energy consumption.

For the United States, the diatomite production data used to prepare table 1 were collected by a survey sent by the U.S. Geological Survey (USGS) to all known mine producers who voluntarily gave a 100% response as to the tonnage and value sold or used, which historically has been considered in these statistics as production. The survey for 2000 covered 7 diatomite-producing companies with 13 separate mining areas and 12 processing facilities in California, Nevada, Oregon, and Washington. Two of these operations were reported as inactive. Major producers were Celite Corp. (Lompoc, CA, and Quincy, WA); Eagle-Picher Industries Inc. (Lovelock and Fernley, NV, and Vale, OR); and Grefco Minerals, Inc. (Burney and Lompoc, CA, and Mina, NV). Smaller producers were Calveras Cement Co. (Burney, CA); CR Minerals Corp. (Fernley, NV); Moltan Co. (Fernley, NV); and Oil-Dry Production Co. (Christmas Valley, OR). California continued to be the leading producing State, followed by Nevada. The combined production of these two States accounted for about 87% of the U.S. production in 2000.

Consumption

Apparent domestic consumption (production sold or used based on USGS's survey plus imports minus exports using trade data furnished by the Department of Commerce; stock data are

Digitized by Google

not available) of diatomite in 2000 was about 547,000 t, a 12% decrease from 625,000 t in 1999.

According to data from the USGS survey, total domestic and export quantities of filter-grade diatomite sold or used by U.S. producers was 446,000 t in 2000, 4% less than in 1999. For absorbents, the second largest category, 96,000 t was consumed, 21% less than in 1999. Filler applications accounted for 95,000 t, 17% more than in 1999, and insulation use increased by 20% to 18,000 t. Other consumption applications decreased by 69% to 21,000 t, special product sales and cement manufacturing constituting the majority of that amount (table 2). Comparing 2000 data with 1995 data for percentage of total use, filter use declined, filler use increased, insulation use remained the same, while absorbent and other uses (mostly special product sales and cement manufacture) increased slightly.

In antiquity, diatomite was used by the Greeks as an abrasive and in making lightweight building brick and blocks. In A.D. 535, blocks of diatomite were used for the 30-meter-diameter dome of the Church of St. Sophia in Istanbul, Turkey (Maurrasse, 1978). However, it only became of industrial interest in Western Europe in the mid-1800s. One of the first uses at that time was as cut blocks and bricks for heat-insulation. In the 1860s, pulverized diatomite became the preferred absorbent and stabilizer of nitroglycerine used by Alfred Nobel to make dynamite. The site of the first U.S. production of diatomite was in Maryland in 1884. By the late 1880s, the very pure, huge deposit near Lompoc became the focus of interest and has continued to dominate the world markets. Diatomite is now used principally as a filter aid; but it has many other applications, such as an absorbent for industrial spills and for pet litter, a filler in a variety of products from paints to dry chemicals, as an insulation material in sawn and molded shapes and as loose granules, a mild abrasive in polishes, and a silica additive in cement and various other compounds.

Commercial diatomite products provide fine-sized, irregular-shaped porous noncaking particles having a large surface area and a high liquid absorption capacity. They are chemically relatively inert, have a low refractive index, are mildly abrasive, have low thermal conductivity with a reasonably high fusion point, can be slightly pozzolanic, are very high in silica, and can be produced and delivered at a cost consistent with customers applications. Sawn shapes have long been used as lightweight building material (especially in 20th century China) and for insulation, primarily thermal (especially the high-clay-containing Danish moler), and continue to account for a significant part of world diatomite production. Dried natural products and calcined products are used in the aforementioned applications. Particulate products are more widely used and can be tailored to fit desired uses by blending various grades of calcined and natural material. The major use, in a great variety of grades, is as a filtration medium for beverages (especially beer and wine), sugar and sweetener liquors, oils and fats, petroleum and chemical processing (including waste drycleaning fluids), pharmaceuticals, and water (potable, industrial process, waste, and swimming pool). A large and growing application is use as an absorbent for industrial spills (oil and toxic liquids) and for pet litter. Another important broad category of use is as a filler, often serving a dual purpose such as an extender and flatting agent in paints and coatings, a bulking and anticaking agent in granular materials, a multieffect component in plastics (including preventing films from sticking), and an extender/absorbent carrier for dry pesticides, pharmaceuticals, catalysts, and other chemicals. Significant other products include an insulation material in bulk (loose), in molded shapes, and in calcium silicate; other insulation products as a component; and a silica additive in various compounds including mortar and portland cement where it is used also for its pozzolanic properties. Worldwide use, including moler, was estimated in 1993 to be almost 50% for filtration, more than 25% for fillers, 17% for insulation, and about 10% for absorption and other applications (Roskill Information Services Ltd., 1994, p. 3).

Commercial diatomite products are offered in a great variety of grades. Principal factors are the size, shape, overall arrangement and proportions of the various types of frustules (particularly the effect on filtration rate, product clarity, and absorption capacity), and content of silica and various impurities, such as certain minerals and chemicals (especially the form of iron, a major impurity), clay, sand, and organics. There are a number of additional specialized application specifications (brightness/whiteness and abrasive hardness). Free crystalline silica content, although normally low, is also required by some environmental regulations, particularly for calcined products. A major influence on the grade is the extent of processing within three broad classifications: naturally milled and dried; plain ("straight") calcined (to 1,000° C); and flux-calcined (to 1,200° C with the addition of up to 10% of sodium compounds, such as soda ash, salt, or sodium hydroxide). Calcining removes organics, increases filtration rate (surface area is reduced by fusing more delicate structures of particles and sintering them into small clusters resulting in larger particle size and increased pore size), oxidizes iron (changing the buff to gray colors common in crude ore feed to pink or white), increases specific gravity, and increases particle hardness; but also disadvantageously produces free silica. Flux-calcining significantly affects the physical and chemical properties and makes a white product. Most filter grades are calcined.

Prices

The calculated weighted average unit value of diatomite sold or used by U.S. producers during 2000, using USGS survey data, was $256 per metric ton f.o.b plant, an 8% increase compared with $238 per ton in 1999 (table 3). Concomitantly, the average value per ton for filter use was down about 11% from the 1999 value. The average values per ton in 2000 for filler use and absorbent use decreased by about 16% and 19%, respectively. Comparing unit values in 2000 with those in 1995, in current 2000 dollars, the calculated weighted average unit value has increased by $7 per ton from $249. The filter grade product price per metric ton in 2000 was $29 less than in 1995. The filler grade unit value in 2000 was $45 less than the $302 price in 1995. Data on other grades are insufficient for accurate comparisons, although unit values for insulation grades appear to have decreased, and unit values for absorbent grades appear to have increased.

Foreign Trade

Export and import data presented herein are from the U.S. Census Bureau and of limited accuracy because of producer-reported inconsistencies as well as lack of detail for the various

Digitized by Google

materials specified in the 2000 Harmonized Tariff Schedule (HTS) of the United States issued by the U.S. International Trade Commission.

Exports of diatomite from the United States in 2000 were 131,467 t according to the census data, which accounted for about 19% of all grades of domestic production sold or used as shown in the USGS survey and were 7% greater than 1999 exports (table 4). The data are issued under code 2512 of the HTS, described as applying to natural and straight-calcined diatomite, but industry sources indicate that exports also include some flux-calcined material. Flux-calcined material, however, according to HTS explanatory notes issued by the World Customs Organization of which the United States is a signatory member, is included under another code (code 3802.90.20.00) where, unfortunately, it cannot be separately identified from activated clays. Similarly, heat-insulating mixtures and sawn and molded unfired shapes of diatomite are in an "other" data classification (code 6806.90.00.90) and are not exclusively identified as diatomite. Also, fired sawn and molded shapes of diatomite are covered in a separate category with data (code 6901) that are not exclusively diatomite.

Industry information indicates that actual total exports of diatomite products can be estimated as a minimum of 300,000 metric tons per year (t/yr), which is about 44% of domestic mine production sold or used in 2000 according to the USGS survey. Industry sources suggest that 75% or more of exports are flux-calcined with the balance being mostly natural or straight calcined grades and only a small portion being material described in codes 6806 and 6901 of the HTS.

Products were exported to 74 countries according to the U.S. Census Bureau data. Main export markets were Germany (32,472 t), Canada (19,625 t), Japan (11,892 t), Belgium (9,136 t), Australia (8,698 t), and the United Kingdom (5,351 t), making up slightly more than 66% of the total exports reported. Based on the available data, the average unit value of exported diatomite was $310 per ton free alongside ship, compared with $324 per ton in 1999 and $360 per ton in 1994. Because the data may not include all the higher value material, as discussed above, actual average unit values may be higher.

Import data available for diatomite show 529 t coming from five countries. In descending order, France provided 34%, followed by China with 30%, with the remainder coming from Italy, Spain, and Mexico.

World Review

China continued to show steady growth in diatomite production in 2000, averaging an increase of 7,500 t/yr since 1998. Japan's production remained essentially the same in 2000 as that of 1999. For 2000, world output was estimated to be 1.89 Mt, which was a decrease compared with 1999 and the lowest global tonnage since 1995 (table 5). Major producers in 2000 were the United States at 36%, followed by China at 18%, Japan with 10%, Denmark at about 10% (all moler products), some former Soviet Union countries and France, each with about 4%. Mexico, Spain, Peru, and the Republic of Korea, in decreasing order of production, were the next ranking producers.

Outlook

The diatomite market appears to remain mature and generally stable at the close of the 20th century. Industry representatives expect the next 5 years to be similar to the past 5 years; increased energy costs and possible global overcapacity, however, may represent impediments to future expansion. The past encroachments into filter applications by more advanced technology (ceramic, polymeric, and carbon membranes) apparently are not of major concern to producers, possibly because of cost factors. Disposal of diatomite waste, however, is a problem not fully resolved by recycling. Emerging markets for diatomite include use in biotechnology and pharmaceuticals and as a nontoxic insecticide (Crossley, 2000, p. 135). The problem of free crystalline silica associated with diatomite, particularly when calcined, continues to be of concern.

EXPLOSIVES

By Deborah A. Kramer

Domestic survey tables were prepared by Feri Naghdi, statistical assistant.

In 2000, U.S. explosives production was 2.57 million metric tons (Mt), a 21% increase from that of 1999; sales of explosives were reported in all States. Coal mining, with 67% of total consumption, continued to be the dominant use for explosives in the United States. Kentucky, Virginia, Wyoming, West Virginia, and Pennsylvania, in descending order, were the largest consuming States, with a combined total of 51% of U.S. sales.

Legislation and Government Programs

On October 13, the Committee for Fair Ammonium Nitrate Trade filed a petition with the U.S. International Trade Commission (ITC) alleging that ammonium nitrate from Ukraine was being sold in the United States at less than fair value. As a result, the ITC began an antidumping investigation of imports of ammonium nitrate from Ukraine and determined that there was a reasonable indication that the domestic industry was being injured (U.S. International Trade Commission, 2000, p. 1-19). The International Trade Administration (ITA) of the U.S. Department of Commerce began its investigation into the antidumping allegation in November and made a preliminary determination in March 2001. According to the ITA's investigation, the estimated dumping margin for J.S.C. "Concern" Stirol was 113.38% ad valorem. The Ukraine-wide rate, which was applicable to all other producers and exporters, was also 113.38%. The ITA also determined that critical circumstances existed. A final determination was set to be completed 105 days after the notice was published in the Federal Register (U.S. Department of Commerce, 2001).

The Bureau of Alcohol, Tobacco and Firearms (ATF) of the U.S. Department of the Treasury was considering amending its regulations to require licensed importers of explosive materials to place the same identification marks on imported explosive materials that are required on explosive materials that are manufactured in the United States. The Institute of Makers of Explosives (IME), who initiated the request, expressed concern that the unidentified explosives could pose a significant safety and security hazard. The ATF was requesting comments from the public regarding the proposed change; comments were due by January 12, 2001 (U.S. Bureau of Alcohol, Tobacco and Firearms, 2000).

Production

Sales of ammonium-nitrate-based explosives (blasting agents and oxidizers) were 2.53 Mt, a 21% increase from that of 1999, and accounted for 99% of U.S. industrial explosives sales. Production of permissibles declined, but production of other high explosives increased (table 1). Figure 1 shows how sales for consumption have changed since 1991.

Because of the sharp decrease in U.S. explosives production from 1998 to 1999, followed by a corresponding sharp increase from 1999 to 2000, the 1999 data appear to be anomalous. Because coal production is the principal driver of explosives consumption, the sharp changes in explosives sales in these years would be expected to be reflected by a corresponding change in coal production. This, however, was not the case. From 1998 to 1999, U.S. coal production declined by about 1.5%. This small decrease was not enough to cause a decline of 28% in explosives sales. This anomaly is particularly evident in the sales to Wyoming where explosives sales declined by 70% from 1998 to 1999, yet coal production in the State actually increased by 7%. These sharp drops in explosives sales from 1998 to 1999 were followed by sharp increases from 1999 to 2000, again without a corresponding change in coal production. This would indicate that there were significant reporting errors in 1999.

Companies contributing data to this report, including those that are not members of the IME, are as follows (nonmembers are denoted by an asterisk):

Accurate Energetic Systems LLC
Apache Nitrogen Products Inc. *
Austin Powder Co.
Baker Atlas International
Coastal Chem Inc. *
Daveyfire Inc.
Douglas Explosives Inc.
Dyno Nobel Inc.
El Dorado Chemical Co.
The Ensign-Bickford Co.
Explosives Technologies International Inc. (ETI)
D.C. Guelich Explosives Co.
General Dynamics OTS Hitech Inc.
Jet Research Center
LaRoche Industries Inc. *
Mining Services International Corp.
W.A. Murphy Inc.
Nelson Brothers Inc.
Nitram Inc. *
Nitrochem Corp.
Orica USA Inc.
Owen Oil Tools Inc.
PCS Nitrogen Corp. *
St. Lawrence Explosives Corp.
Schlumberger Perforating Center
Senex Explosives Inc.
Slurry Explosives Corp.
Vet's Explosives
Viking Explosives and Supply Co.

LaRoche Industries Inc. filed for chapter 11 bankruptcy in May. In August, LaRoche announced the sale of its ammonium nitrate facilities in Alabama, Illinois, Missouri, and Utah to Orica LLC, a unit of Orica Ltd., an international manufacturer and distributor of explosives. After the U.S. Bankruptcy Court in Delaware approved the sales, Orica then sold the Cherokee, AL, and Crystal City, MO, facilities to LSB Industries Inc.,

Digitized by Google

which planned to operate these facilities under its El Dorado Chemical Co. subsidiary (Green Markets, 2000).

Dyno Nobel Inc. and Orica USA Inc. established a joint-venture manufacturing company, Geneva Nitrogen Inc., to operate the Geneva, UT, industrial-grade ammonium nitrate facility that Orica acquired from LaRoche Industries. Through the joint venture, both companies will own 50% of the plant, as well as one-half of the associated production volume of 100,000 metric tons per year (t/yr). Each company planned to market its 50% portion of the produced volume separately (Dyno Nobel ASA, November 2, 2000, Dyno Nobel forms US nitrogen plant jv, accessed February 6, 2001, via URL http://www.dynonobel.com/dninternet/home1.nsf).

In February, ICI Explosives USA Inc. sold its remaining ammonium nitrate production facilities in Joplin, MO, to Joplin Manufacturing Inc., which is a unit of Orica, for approximately $5.2 million. Orica was committed to purchasing the output of the plants for 4 years as part of the original international explosives acquisition from ICI plc in May 1998 (ICI plc, February 24, 2000, ICI sells US explosives plants to ORICA, accessed June 13, 2000, via URL http://www.ici.com/pressoffice).

Consumption

Coal mining, with 67% of total explosives consumption, remained the largest application for explosives in the United States. According to the U.S. Energy Information Administration of the U.S. Department of Energy (DOE), for the first time in 40 years, coal production declined for 2 years in a row and reached 976 Mt, about 2.3% less than that in 1999 (Fred Freme, 2001, U.S. coal supply and demand—2000 review, accessed June 1, 2001, at URL http://www.eia.doe.gov/fuelcoal.html). The production decline was attributed to a drawdown in stocks and a lack of excess production capacity at some mines.

Wyoming, West Virginia, and Kentucky, in descending order, led the Nation in coal production, accounting for 59% of the total, and were among the largest explosives-consuming States, accounting for 37% of total U.S. explosives sales.

Quarrying and nonmetal mining, the second-largest consuming industry, accounted for 14% of total explosives sales; metal mining, 9%; construction, 8%; and miscellaneous uses, 2% (table 2). Kentucky, Virginia, Wyoming, West Virginia, and Pennsylvania, in descending order, were the largest consuming States, with a combined total of 51% of U.S. sales (table 3).

The value of new construction increased by 1.7%, based on constant 1996 dollars (U.S. Census Bureau, 2001, Value of construction put in place, accessed June 20, 2001, at URL http://www.census.gov/prod/ 2001pubs/c30-0103.pdf). Federal Reserve Board indices indicated that the industry growth rate for metal mining from 1999 to 2000 was -4.2% and that the growth rate for stone and earth minerals was -1.8% (Federal Reserve Board, 2000, Industrial production and capacity utilization—Federal Reserve statistical release G17, accessed June 20, 2001, at URL http://www.federalreserve.gov/releases/G17/Revisions/20001205/table6.txt).

Classification of Industrial Explosives and Blasting Agents.—Apparent consumption of commercial explosives used for industrial purposes in this report is defined as sales as reported to the IME. Commercial explosives imported for industrial uses were included in sales.

The principal distinction between high explosives and blasting agents is their sensitivity to initiation. High explosives are cap sensitive, whereas blasting agents are not. Black powder sales were minor and were last reported in 1971. The production classifications used in this report are those adopted by the IME.

High Explosives.—Permissibles.—The Mine Safety and Health Administration approved grades by brand name as established by National Institute of Occupational Safety and Health testing.

Other High Explosives.—These include all high explosives except permissibles.

Blasting Agents and Oxidizers.—These include (1) ammonium nitrate-fuel oil (ANFO) mixtures, regardless of density; (2) slurries, water gels, or emulsions; (3) ANFO blends containing slurries, water gels, or emulsions; and (4) ammonium nitrate in prilled, grained, or liquor (water solution) form. Bulk and packaged forms of these materials are contained in this category. In 2000, about 93% of the total blasting agents and oxidizers was in bulk form.

World Review

Australia.—Dyno Nobel officially opened its Queensland Nitrates Pty. Ltd. facility in October. The $240 million complex has the capacity to produce 180,000 t/yr of ammonium nitrate. Much of the plant's output was expected to be marketed to the local coal-mining industry and to complement Dyno Nobel's other manufacturing facilities in the area—its explosives plant at Bajool and its detonator assembly facility at Helidon (Dyno Nobel ASA, October 6, 2000, Opening of Dyno Nobel AN complex, accessed February 6, 2001, at URL http://www.dynonobel.com/dninternet/home1.nsf).

Europe.—Orica announced that it would form a joint venture with Accept Corp. of Kazakhstan to manufacture and market explosives in Kazakhstan. The joint venture will be called Orica Kazakhstan, and Orica would own 80% of the company, and Accept, the remaining 20%. Orica Kazakhstan would be the first modern explosives manufacturer to be established in the country. The $100 million per year explosives requirements of Kazakhstan's mining industry have been supplied by imports, predominantly from Russia (Orica Ltd., May 18, 2000, Orica establishes Kazakhstan venture, accessed June 12, 2000, via URL http://www.orica.com/business/cor/wcor00009.nsf/webnav2/News+Releases?OpenDocument).

In October, Orica announced that it had signed a letter of intent to acquire the German firm Dynamit Nobel AG for about $38.2 million. The acquired business includes manufacturing sites at Troisdorf and Wurgendorf in Germany and Sirgala in Estonia. In addition, Dynamit Nobel is a major manufacturer of detonators for commercial explosives with production facilities at Troisdorf. The acquisition also would give Orica full ownership of Precision Blasting Systems GmbH, a joint venture formed in 1999 with Dynamit Nobel to develop and manufacture electronic detonator systems based on the combined technology of both companies (Orica Ltd., August 31, 2000, Orica planning European explosives acquisition, accessed February 6, 2001, via URL http://www.orica.com/business/cor/wcor00009.nsf/webnav2/News+Releases?OpenDocument).

Kimit AB and Orica signed a letter of intent to form a joint venture to manufacture, supply, and distribute commercial explosives in the Nordic countries. The joint venture was

Digitized by Google

expected to have initial sales of approximately $3.6 million. Orica Europe Ltd. would hold 51% and Kimit would hold 49% of the shares of the new company (Orica Ltd., October 9, 2000, Orica and Kimit to form Scandinavian explosives venture, accessed March 13, 2001, via URL http://www.orica.com/business/cor/wcor00009.nsf/webnav2/News+Releases?OpenDocument).

South America.—Orica formed a joint-venture company with Merand Group in Venezuela in order to increase its participation in the Venezuelan explosives market. The joint-venture company was expected to operate under the name Orica Venezuela C.A. The new company signed an agreement with Compañía Anónima Venezolana de Industrias Militares (CAVIM), a state-owned company that regulates the manufacture of industrial explosives in Venezuela, to build and operate a plant to supply CAVIM with the bulk explosives needs of its customers for at least the next 5 years. Orica estimated that the Venezuelan market for industrial explosives has a value of about Australian $35 million and was expected to grow at around 10% per year (Orica Ltd., April 27, 2000, Orica forms new company in Venezuela, accessed June 12, 2000, via URL http://www.orica.com/business/cor/wcor00009.nsf/webnav2/News+Releases?OpenDocument). Orica's existing Latin American explosives interests in the Americas include manufacturing operations in Argentina, Brazil, Chile, and Mexico.

Current Research and Technology

After at least 20 years of efforts, scientists at the University of Chicago synthesized the compound octocubane ($C_8N_8O_{16}$). Octocubane consists of a cube of eight carbon atoms with nitro (NO_2) groups attached to each carbon atom. This material could be one of the most powerful explosives developed. It could be twice as powerful as trinitrotoluene (TNT), and it is thought to be 20% to 25% more energetic than High-Melting eXplosive (HMX), one of the most powerful military explosives in use today. Unlike these materials, however, octocubane is shock insensitive, which means it is much safer to handle. In addition, octocubane should burn into carbon dioxide and nitrogen, which, unlike some other explosive materials residues, should not harm the environment. Scientists at the Naval Research Laboratory are investigating the structural, electronic, and vibrational properties of octocubane (Wu, 2000).

The Defense Advanced Research Projects Agency developed a prototype system that can detect plastic landmines containing TNT in the field. The prototype is based on quadrupole resonance technology that uses an externally applied radio-frequency, magnetic-field pulse at a frequency that is specific to individual explosive compounds. When the pulse is aimed at the ground, it excites the molecules of any explosives present, generating a characteristic response that can be measured and analyzed by the system. In a test, the prototype detected all of the antipersonnel and antitank landmines with no false alarms. Based on these results, the U.S. Army and the U.S. Marine Corps were initiating programs to develop the system for field use (Defense Advanced Research Projects Agency, 2000).

Chemical Detection Technologies Inc. developed a new device that the company claimed could clear 500 to 2,000 square meters of land per hour of landmines, a process that can take 2 to 3 days with humans and trained dogs. The device uses low-energy x rays that make nitrates in the soil fluoresce; this fluorescence is captured by a specially designed germanium detector. The spectroscopic emission band of the nitrates is compared with the spectroscopic emissions of known explosives to determine its type. Although nitrates that are found naturally in the soil and nitrates from fertilizers will also fluoresce, their chemical signatures are different from those of the explosives in landmines, and the device should not be confused. The new device has been through preliminary field tests in Croatia, and the company planned to complete more testing (Photonics Spectra, 2000b).

The U.S. Navy was testing two new systems to accurately detect mines underwater. The two systems produce video images of mines at near television resolution in real time; one detects mines at or near the water's surface, the other detects mines on the bottom. The technology uses a laser, a streak-tube receiver (similar to a photomultiplier tube), and conventional digital recording technology. When the laser detects an image, it is captured by the streak tube and digitally recorded. Successive images are processed into a three-dimensional image. A human operator is still required to determine which image is that of a mine. Although the new technology is fast, offers higher resolution, and is more rugged than conventional mine-detection systems, it only covers a small area at a time. Because of this problem, the new technology will probably be used as an adjunct to traditional methods in specific trouble areas (Photonics Spectra, 2000a).

Through its Sandia National Laboratories, the DOE was undertaking several research projects on explosives technology. In one of the projects, Sandia was investigating methods of treating water saturated with organic explosives such as TNT and cyclotrimethylenetrinitramine (RDX), which is typical of water that would be generated at explosives-producing plants. The objective is for the treated water to meet U.S. Environmental Protection Agency requirements for discharge into sanitary sewers or to be able to be recycled for further use in processing explosives. Sandia scientists conducted a series of experiments that used different combinations of ultraviolet light, a catalyst (titanium dioxide in most cases), oxidants (hydrogen peroxide or ozone), and biodegradation (decomposition by bacteria). They applied these treatments in various combinations, studying the potential of photocatalysis both as a single-treatment process and as a pretreatment to biodegradation. The researchers found that when photocatalysis preceded biodegradation, both explosives decomposed to near-zero toxicity. Future work was projected to include optimizing the process variables and constructing a pilot plant (Sandia National Laboratories, [undated], Wastewater treatment, accessed June 15, 2001, at http://www.sandia.gov/explosive/projects/pinkwater.htm).

Also at Sandia, researchers are working with entomologists from the University of Montana to determine if foraging bees can be used to detect buried landmines. In many developing countries, thousands of acres of land lie unused because farmers are afraid to work their fields fearing buried landmines. As bees forage for nectar and pollen, they attract particles of dust, soil, and pollen to their bodies and bring samples back to the hive. In doing so, they provide a chemical survey of an area extending a mile or more from the hive in all directions. The research team is establishing two bee colonies in a remote test area that has many buried mock landmines. The colonies will live in highly instrumented "honeybee condos" that automatically count the number of times bees fly in and out of the hive, to track the bees flight activity. Pollen, dust, air, and other samples collected by the bees and brought to the hives

Digitized by Google

will be analyzed for trace amounts of explosives. Two other control colonies will be established to provide baseline data for comparison. The entomology team has demonstrated that by providing a new bee colony with feeders tainted with a marker chemical, then gradually moving the feeders farther from the hive and eventually removing them, bees can be trained to forage wherever they smell the chemical. If bees can be trained to seek TNT, the team may attach small diodes onto the backs of several hundred TNT-trained bees. Then, using a handheld radar tracking device, they will chart where those bees go to determine whether they tend to forage near the locations of known landmines (Sandia National Laboratories, [undated], Sandia, University of Montana researchers try training bees to find buried landmines, accessed June 15, 2001, at URL http://www.sandia.gov/explosive/projects/minebees.htm).

Sandia is helping to develop a portable mine-detection system that incorporates ion mobility spectrometry, which is the same technology that is used to check airline passengers. This technology is expected to be capable of quickly detecting and classifying minute quantities of explosive molecules. The system incorporates a new Sandia-developed concentration technology that potentially can chemically amplify the source strength thousands of times. The project originally was directed at detecting sea mines and unexploded ordnance in shallow water and is sponsored jointly by the DOE and the Department of Defense (Sandia National Laboratories, [undated], Sandia Labs developing means to sniff out mines chemically and electronically, accessed June 15, 2001, at URL http://www.sandia.gov/explosive/projects/landmine.htm).

An instrument that can detect tiny explosions could lead to an inexpensive hand-held device to screen people and luggage at airports or to detect landmines. The device, being developed at the DOE's Oak Ridge National Laboratory, is based on miniature micromachined silicon cantilevers one-tenth the width of a human hair that can detect tiny forces caused by heat-induced nanoexplosions. The instrument, which has sensitivity in the parts-per-trillion range, works by absorbing TNT molecules given off by explosives. As the semiconductor material absorbs the TNT and is heated with power from a battery, the TNT molecules undergo tiny explosions that are detected by an optical beam. In addition, by scanning an appropriate temperature range, researchers can use this technology to detect many explosive molecules, including those used in plastic explosives (Oak Ridge National Laboratory, February 21, 2000, ORNL technology detects explosives with mini-explosions, accessed June 15, 2001, at URL http://www.ornl.gov/Press_Releases/archive/mr20000221-00.html).

Outlook

The DOE projects a 4.5% increase in coal production in 2001 and a 1.4% increase in production in 2002. Almost all of the production increase is projected to come from the western region. A decrease in production is projected to occur in the interior region, and a small increase in production is projected in the Appalachian region for 2001 and 2002 (U.S. Energy Information Administration, May 2001, Short-term energy outlook, accessed June 20, 2001, at URL http://www.eia.doe.gov/pub/forecasting/steo/oldsteos/may01.pdf). If these projections are correct, explosives consumption should increase in 2001 and then remain about the same in 2002. Because most of the increase in coal production is forecast for the western region, explosives consumption is not expected to increase at the same pace as coal production; the lower overburden-to-matrix ratio in the western region will lead to a slower growth in explosives consumption. Aberrations in weather patterns, however, could have a substantial impact on U.S. coal demand, because most of it is used for electricity production. Changes in coal demand obviously will have an impact on the explosives demand in the United States.

In the construction and quarrying sectors, a gradual increase in demand for construction aggregates is anticipated on the basis of the expected volume of work on the U.S. infrastructure that will be financed by the new Transportation Equity Act for the 21st Century.

FELDSPAR AND NEPHELINE SYENITE

By Michael J. Potter

Domestic survey data and tables were prepared by Raymond I. Eldridge III, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

Feldspar was used in commerce in the form of aluminosilicates that contained calcium, potassium, and sodium. Nepheline syenite, which is a light-colored, silica-deficient feldspathic rock made up mostly of sodium and potassium feldspars and nepheline, was not mined in the United States but was imported from Canada for use in the glass and ceramic industries.

Feldspar

In glassmaking, alumina from feldspar improves product hardness, durability, and resistance to chemical corrosion. In ceramics, feldspar is used as a flux, lowering the vitrifying temperature of a ceramic body during firing and forming a glassy phase.

In 2000, U.S. shipments (domestic sales) of glass containers, a major end use of feldspar, were about 3% less than in 1999 (U.S. Census Bureau, February 2001, Glass containers—Current industrial reports, accessed April 23, 2001, at URL http://www.census.gov/cir/www/m32g.html). In the housing and remodeling markets, feldspar was used in glass fiber insulation, sanitaryware, and tile. Housing starts were an estimated 1.59 million, which was about 4% less than in 1999 (U.S. Census Bureau, January 18, 2001, Housing starts and building permits in December 2000, accessed May 4, 2001, at URL http://www.census.gov/const/C20/c20_0012.txt).

Ceramic tile consumption (including imports) in the United States increased each year during the 1990s to 206.9 million square meters (Mm^2) in 1999 from 85.1 Mm^2 in 1991. Imports accounted for approximately 67% of the tile consumed in the United States in 1999 (Daniels, 2000).

Production.—In 2000, U.S. production of marketable feldspar was an estimated 790,000 metric tons (t) with a value of $44.5 million (table 1). Feldspar was mined in seven States, which were, in descending order of output, North Carolina, Virginia, California, Georgia, Oklahoma, Idaho, and South Dakota. North Carolina accounted for about 44% of the total. Mining was by 9 companies with a total of 12 plant operations—4 in North Carolina, 3 in California, and 1 in each of the remaining States listed above.

Domestic production data for feldspar were collected by the U.S. Geological Survey by means of a voluntary survey. Of the 12 known plant operations, 6 responded by the data closeout date. The six operations represented about 60% of the year 2000 production shown in tables 1 and 2. Data for the remaining six operations were estimated from prior year production levels.

Oglebay Norton Co. acquired the mica operations of Franklin Industrial Minerals, located in New Mexico and North Carolina. The North Carolina site also produced feldspathic sand, kaolin, quartz sand, and potassium feldspar. The operations were incorporated under a wholly owned subsidiary, Oglebay Norton Specialty Minerals, Inc. (North American Minerals News, 2000).

Consumption.—Of the U.S. feldspar sold or used, 66% went into the manufacture of glass, including glass containers and glass fiber. Pottery (including electrical insulators, sanitaryware, tableware, and tile) and other uses, such as fillers,

Feldspar and Nepheline Syenite in the 20th Century

In 1900, U.S. feldspar production was about 22,500 metric tons with a value of about $181,000. Quantitative end-use data were not available for that year, but uses were reported to be floor and wall tiles, glass, pottery, scouring soaps, and wood fillers. Feldspar was produced by selective mining and hand sorting of coarse-grained pegmatites from deposits located in Connecticut, Maine, New York, and Pennsylvania. Material was processed by dry crushing and grinding. Around 1910, uses for feldspar included enamelware, true porcelain, vitrified sanitaryware, and whiteware. Feldspar was used in both ceramic bodies and glazes. A major development in processing technology was the flotation process developed in 1939 in a cooperative effort between the U.S. Bureau of Mines and the feldspar industry. This process enabled treatment of a broader range of ores in which feldspar was more intermixed with quartz, mica, and other accessory minerals. The first commercial flotation plant began operation in North Carolina in 1946.

Nepheline syenite, mined in Ontario, Canada, is a feldspathic rock that, when processed, competes with feldspar in glass, pottery, and filler use. Official recording of U.S. imports of nepheline syenite began in 1939, when about 26,500 tons were imported. U.S. imports of nepheline syenite reached a high of about 497,000 tons in 1978.

In 2000, U.S. feldspar production was 790,000 tons. End uses were glass (66%) and pottery and other uses (34%). Feldspar use in glass containers faced competition from recycled glass, metal, paper, and plastic containers. Imports of nepheline syenite were 356,000 tons. Total world production of feldspar in 2000 was about 9 million tons. Italy produced 2.6 million tons; Turkey, 1.1 million tons; and France, 600,000 tons. Output came from at least 46 other countries.

Digitized by Google

accounted for the remaining 34% (table 4). Tableware included plates, mugs, cups, and saucers and was categorized in the trade based on the contained proportions of clay, kaolin, quartz, and feldspar and on the firing process. Earthenware, the most common form of tableware and originally considered to be the cheapest form, has been offered in highly decorated versions with a more upscale image. Stoneware is earthenware given more strength by being fired at high temperature. It is nonporous and commands a higher price. Porcelain is semitransparent earthenware made by combining white china clay with either powdered glass or other hard materials. Bone china is a combination of porcelain and bone ash; fine bone china is an even thinner version (Selzer, 2000).

Prices.—The prices for ceramic grade sodium feldspar, 170-250 mesh, ex-works United States, increased at yearend 2000 by about $3 per ton at both lower and upper ends of the price range to about $67 to $80 per ton. This increase in not reflected in table 5. Ceramic grade feldspar, 200 mesh, bagged, ex-works Eastern United States, increased by about $7 per ton compared with the price earlier in the year to about $139 per ton; this was also a $34 increase per ton compared with the price in December 1999. Glass grade feldspar, 30 mesh, bulk, ex-works Eastern United States, increased by about $8 per ton at the upper end of its range to $57 per ton (not listed in table 5) (Mineral Price Watch, 2001).

World Review.—**Europe.**—After 1989-90, inexpensive natural gas was no longer available to ceramic factories in Eastern Europe from the former Soviet Union. With credit from Western European kiln manufacturers, a number of shuttle and tunnel kilns were put into service in Eastern and Central Europe during the mid-1990s. Private housing development in Eastern and Central Europe required large quantities of building materials, including sanitaryware, ceramic tiles, and roofing tiles. Western sanitaryware manufacturers began investing in some of the ceramic plants and brought marketing expertise. The quality of the sanitaryware and tile improved significantly, and most local producers were exporting at least 50% of their output (MacQuaid, 2000).

Mexico.—Housing construction was reported to consist of 370,000 to 380,000 units per year. The sanitaryware, or vitreous china, market in Mexico amounted to about 5.5 million units per year, including wash basins and other bathroom fixtures and accessories. Remodeling was another significant outlet for these items. Mexico exported about 70% of its sanitaryware production to the United States. A typical liquid slurry feed material (slip) for sanitaryware consisted of 22% to 27% ball clay, 26% to 35% kaolin, 22% to 32% silica, and 18% to 27% feldspar. The kaolin and ball clay were imported primarily from the United States; in Mexico, exploration for industrial minerals was still in the early stages (Harris, 2000).

Spain.—Feldspar output in 2000 was an estimated 425,000 t (table 8). End usage was 64% in ceramics, such as glazes, porcelain, sanitaryware, and tiles; 32% in glass; and 2% in other applications, such as paints, plastics, and rubber. Feldspar imports were about 350,000 metric tons per year (t/yr), of which 250,000 t/yr was sodium feldspar from Turkey (Regueiro y Gonzalez-Barros and Marchan Sanz, 2000).

Among Spain's largest feldspar producers were Industrias del Cuarzo SA, with output of 125,000 t/yr of potassium feldspar and 60,000 t/yr of feldspathic sands from its eolian (wind deposited) sands operation at Carrascal del Rio, Segovia; Compania Minera de Rio Piron, with around 100,000 t/yr of potassium feldspar from eolian sand deposits at its operation in Navas del Oro, Segovia; Llansa SA, producing about 80,000 t/yr of potassium/sodium and sodium feldspar from a pegmatite deposit in Llansa, Girona; and Basazuri SL, with 80,000 t/yr of albite in Lugo Province. Spain's reserves of feldspathic sands were said to be the largest in Europe (Regueiro y Gonzalez-Barros and Marchan Sanz, 2000).

Outlook.—According to Market Studies, Inc., Raleigh, NC, the dollar volume of the U.S. dinnerware market in 1998 was $1.4 billion. Demand for semivitreous china dinnerware increased by 7% in 1998, while that of vitreous china increased by 5.2%. Sales of semivitreous china were about 54% of the market, or $729 million. Continued growth in sales for the semivitreous category was projected to increase at a rate of 4.5% per year through 2003, reaching $910 million by 2003. Market Studies also projected that overseas demand for vitreous china dinnerware would remain unchanged through 2003. However, demand for U.S. semivitreous china dinnerware exports could increase at a rate of 5.7% per year, reaching $30 million by 2003 (Ceramic Industry, 1999).

The Cleveland, OH, market research company The Freedonia Group, Inc., projected U.S. demand for glass containers wold grow more slowly than for plastic containers in the near term. The Freedonia study also projected that the market for glass bottles should improve somewhat because their replacement in the soft drink and milk markets largely has been completed, that there would be a decline in loss of market share to plastics in bottled water and distilled spirits, and that metal cans would continue to account for about one-half of the beverage container market in unit terms (Ceramic Industry, 2000).

Consumption of container glass was showing growth in the beer and soft drink markets in such areas as China and Southeast Asia. On a worldwide basis, however, the ceramic industry was projected to show stronger growth than glass containers (Roskill Information Services Ltd., 1999, p. 4).

Nepheline Syenite

In glass and ceramics, nepheline syenite, like feldspar, provides alkalis that act as a flux to lower the melting temperature of a glass or ceramic mixture, prompting faster melting and fuel savings. In glass, nepheline syenite also supplies alumina, which gives increased resistance to scratching and breaking, improved thermal endurance, and increased chemical durability.

Canada and Norway produced nepheline syenite for glass and ceramic use. In Ontario, Canada, Unimin Canada, Ltd., operated two plants at its Blue Mountain deposit, about 175 kilometers northeast of Toronto. Output was about 617,000 t in 1998. An estimated 70% of the output went into glass, especially container glass and glass fiber. About 15% was used in ceramic applications and 15% in pigments and fillers (Guillet, 1994, p. 724). An estimated 60% of the output was shipped to the United States, 20% to the Canadian market, and 20% to European countries (Bolger, 1995, p. 31).

In Norway, North Cape Minerals AS produced about

Digitized by Google

320,000 t of nepheline syenite in 1998 from an underground mine on the Arctic island of Stjernoya. An estimated 70% of the output went to glass manufacturing, 28% to ceramics, and 2% to filler (Bolger, 1995, p. 38).

In the European Union, the glass container recycling rate was more than 50% of glass container consumption. The growing trend to use recycled glass in glass manufacture was reducing the demand for nepheline syenite and feldspar. The increasing use of alternative packaging containers made of such materials as aluminum, coated paper, and plastic also was having an adverse effect on glass container consumption (Saller, 1999).

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through April 24, 2001.

3/ In adddition to the countries listed, Czech Republic, Madagascar, Namibia, and Slovakia produce feldspar, but output is not officially reported; available general information is inadequate for the formulation of reliable estimates of output levels.

4/ Reported figure.

5/ Data are for fiscal years beginning April 1 of that stated.

6/ In addition, the following quantities of aplite ore were produced in metric tons: 1996--365,580 (estimate); 1997--310,000 (estimate); 1998--310,000 (revised estimate); 1999--330,000 (revised); and 2000--330,000 (estimate).

7/ Excludes nepheline syenite.

8/ Includes pegmatite.

FERROALLOYS

By Michael D. Fenton

Domestic survey data and tables were prepared by Jo-Ann S. Sterling, statistical assistant, and the world production table was prepared by Glann J. Wallace, international data coordinator.

Ferroalloys are alloys of iron that contain one or more other chemical elements. These alloys are used to add these other elements into molten metal, usually in steelmaking. The top five ferroalloy producers in the world in 2000, in decreasing order, were China, South Africa, Norway, Russia, and Ukraine. Ferroalloys impart distinctive qualities to steel or cast iron or serve important functions during the production cycle. The ferroalloy industry is closely associated with the iron and steel industry, its largest customer. World production in 2000 of the bulk ferroalloys chromium, manganese, and silicon, was estimated at 16.6 million metric tons (Mt). U.S. bulk ferroalloy reported consumption in 2000 was 1.1 Mt.

The principal ferroalloys are those of chromium, manganese, and silicon. Manganese is essential to the production of virtually all steels and is important to the production of cast iron. Manganese is used to neutralize the harmful effect of sulfur and as an alloying element. Silicon is used primarily for deoxidation in steel and as an alloying element in cast iron. Boron, chromium, cobalt, columbium, copper, molybdenum, nickel, phosphorus, titanium, tungsten, vanadium, zirconium, and the rare-earth elements are among the other elements contributing to the character of the various alloy steels and cast irons (Brown and Murphy, 1985, p. 265).

Compared with the major ferroalloy-producing countries, U.S. ferroalloy production is moderate in silicon and manganese, but relatively low in other ferroalloy metals. Consequently, U.S. ferroalloy production meets only a small percentage of domestic demand. One important exception is ferrosilicon. For all forms of silicon, the United States has been meeting about 70% of its needs. In countries with competitive mineral resources, the trend is toward production of value added products, particularly in the case of chromium. Because of the unlikely prospect of new or expanded U.S. production and because of the uncompetitive U.S. mineral resources for most of the ferroally metals, the overall domestic ferroalloy production trend is one of decline. Nickel and chromium are prime examples. By 1999, U.S. production of ferronickel and common grades of ferrochromium had ceased. In both cases, when production stopped, resources were low-grade, producers were relying on imported ore for feedstock, and operating costs were high. In contrast, ferrosilicon and manganese ferroalloy production have fluctuated, but have been relatively strong (Sibley and others, 2001, p. 33).

In the major ferroalloys and probably some specialty ferroalloys, alternative materials to ferroalloys use, principally alloy scrap and oxide, overall have gained moderately on ferroalloys use per ton of steel production over the past 20 years. A combination of factors, including technology, availability, and price, is responsible for this general decline in unit consumption of the ferroalloy form, and ferroalloy metal from all sources, for the major ferroalloys in steelmaking. U.S. customer needs for ferroalloys in alloy and stainless steel for a multitude of applications have been and will continue to be strong, even while the steel industry continues to improve processing technology to reduce raw materials needs, and metallurgists develop steel grades with lower alloying metal content and equal or better performance to lower costs. For many stainless steel applications there are no acceptable substitutes, and its key constituents, chromium and nickel, are essential. As technology and industry practices result in greater efficiency of use of ferroalloys, the strong demand for metals in construction, the chemical industry, transportation, and household appliances is expected to more than offset any basic reduction in unit consumption in the future. Competition from other materials, such as plastics and nonferrous metals in the transportation sector, will be strong, but the use of lightweight, high-strength grades is expected to make steel competitive for many years (Sibley and others, 2001, p. 40).

Chromium, manganese, silicon, and other ferroalloys are discussed in more detail, including domestic data coverage and outlook, and U.S. Government stockpile, in the respective commodity chapters in the U.S. Geological Survey Minerals Yearbook. These chapters are also published individually in the Mineral Industry Surveys Annual Review series. The tables in this chapter contain information on all ferroalloys for which data are available.

The major world chromite ore producing countries in 2000 were India, Kazakhstan, South Africa, and Turkey. Brazil, Finland, and Zimbabwe were significant chromite ore producing countries. Most chromite ore was smelted in electric-arc furnaces to produce ferrochromium for use by the metallurgical industry. Stainless steel manufacture consumed most ferrochromium. The country with the largest ferrochromium production was South Africa. China, Finland, India, Kazakhstan, Russia, and Zimbabwe were also significant ferrochromium producing countries. The major stainless steel producing areas of the world—Europe (including Western Europe and Scandinavia), Asia (Japan, Korea, and Taiwan), and the United States—account for about 80% of world stainless steel production.

The ferrochromium industry developed in close proximity to the stainless steel industry. However, the closing of ferrochromium facilities in these historically-producing areas has resulted in the migration of ferrochromium production capacity to chromite-producing areas. The world chromium industry in 2000 operated with production capacity in excess of demand. In South Africa, ferrochromium production capacity was brought on-stream and new furnaces were planned and under construction. Four industry trends were evolving—ferrochromium production using an environmentally friendly, and energy- and recovery-efficient, prereduction, closed-furnace process; chromium recovery from ferrochromium slag; consolidation of ownership in both the ferrochromium and stainless steel production industries; and strategic alliances between the latter two industries.

Manganese ferroalloys, consisting of various grades of

Digitized by Google

ferromanganese and silicomanganese, are used to provide a key ingredient for steelmaking (Matricardi and Downing, 1995, p. 970). Most U.S. supply was imported. The leading foreign source of ferromanganese and silicomanganese was South Africa, whose exports of manganese ferroalloys to the United States were greater than those of the next three largest sources combined (Australia, Kazakhstan, and Mexico). Manganese ferroalloys were produced domestically only at a plant near Marietta, OH, which was owned by France's Eramet. Eramet and Billiton plc of the United Kingdom accounted for a significant portion of the world's production of manganese ferroalloys. Eramet controlled plants in China, France, Italy, and Norway, and Billiton controlled plants in Australia and South Africa. On a country basis, China was by far the largest producer of manganese ferroalloys, with an output greater than that of South Africa and Ukraine combined, the countries with the next largest production.

Demand for silicon ferroalloys is driven principally by the production of steel and cast iron (Dosaj, 1997, p. 1115). On the basis of content, U.S. production of silicon ferroalloys declined to less than 50% of apparent consumption of ferrosilicon because of a significant increase in imports. Norway was the leading source of U.S. imports. China was estimated to be the world's largest producer of ferrosilicon, with production more than twice that of either Norway or Russia, the countries with the next largest production. This chapter includes data for silicon metal, which generally was produced like ferrosilicon in submerged-arc electric furnaces. Silicon metal was not used as a ferroalloy, but rather for alloying with aluminum and for production of chemicals, especially silicones (Dosaj, 1997, p. 1108).

r/ Revised. -- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ FeB, ferroboron, includes other boron materials; FeMn, ferromanganese, includes manganese metal; SiMn, silicomanganese; FeP, ferrophosphorus, includes other phosphorus materials; FeSi, ferrosilicon, includes silicon metal, silvery pig iron, inoculant alloys; FeT, ferrotitanium, includes titanium scrap, other titanium materials.

3/ All or part included with "Steel: Unspecified."

4/ All or part withheld to avoid disclosing company proprietary data.

5/ Included with "Steel: Other alloy."

6/ Included with "Alloys (excluding alloy steels and superalloys)."

7/ All or part included with "Cast irons."

8/ Part included with "Miscellaneous and unspecified."

9/ Includes producer stocks.

TABLE 3
REPORTED U.S. CONSUMPTION OF FERROALLOYS AS ALLOYING ELEMENTS BY END USE IN 2000 1/ 2/

(Metric tons of contained elements unless otherwise specified)

End use	FeCr	FeMo	FeNb	FeNi	FeV	FeW
Steel:						
Carbon	6,990	347	1,370	--	2,110	--
Stainless and heat-resisting	162,000	485	682	13,200	W	(3/)
Other alloy	28,000	2,360	1,090	85	790	(3/)
Tool	1,860	398	(4/)	--	43	(3/)
Unspecified	--	--	--	--	--	(3/)
Total	199,000	3,590	3,140	13,300	2,940	388
Cast itons	5,140	523	--	(5/)	W	--
Superalloys	7,080	W	1,060	--	15	(3/)
Alloys (Excluding alloy steels and superalloys)	1,740	102	W	135	2	(3/)
Miscellaneous and unspecified	W	51	10	(5/)	75	--
Grand total	213,000	4,270	4,210	13,500	3,030	388
Total 1999	212,000 r/	4,350 r/	3,460 r/	12,800 r/	3,160 r/	484
Percentage of 1999	101	98	122	105	96	80
Consumer stocks, December 31	15,100	197	NA	768	299	33

r/ Revised. NA Not available. W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified. -- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ FeCb, ferrocolumbium, including nickel columbium; FeCr, ferrochromium, including other chromium ferroalloys and chromium metal; FeMo, ferromolybdenum, including calcium molybdate; FeNi, ferronickel; FeW, ferrotungsten; and FeV, ferrovanadium, including other vanadium-carbon-iron ferroalloys.

3/ Included with "Total steel."

4/ Included with "Steel: Other alloy."

5/ All or part included with "Alloys (excluding alloy steels and superalloys)."

TABLE 4
FERROALLOY PRICES IN 2000

	High	Low	Average 1/
Chromium:			
Charge-grade ferrochromium 2/	43.00	37.00	41.44
High-carbon ferrochromium 2/	43.00	37.00	40.13
Low-carbon ferrochromium 2/	76.00	60.00	69.33
Columbium:			
High-purity (vacuum-grade) ferrocolumbium 3/	18.00	17.50	17.75
Regular-grade ferrocolumbium 3/	7.00	6.75	6.88
Manganese:			
Medium-carbon ferromanganese 2/	54.00	35.00	46.00
Standard-grade ferromanganese 4/	530.00	450.00	488.00
Silicomanganese 5/	27.50	19.50	23.80
Molybdenum:			
Ferromolybdenum 3/	3.70	2.90	3.50
Molybdenum oxide 3/	2.98	2.15	2.59
Silicon:			
50% ferrosilicon 2/	47.00	43.00	45.00
75% ferrosilicon 2/	39.00	33.00	35.40
Silicon metal 5/	59.00	49.00	54.80
Vanadium, ferrovanadium 3/	6.80	3.50	5.05

1/ Annual time-weighted average.
2/ Cents per pound of contained element.
3/ Dollars per pound of contained element.
4/ Dollars per long ton.
5/ Cents per pound.

Total	16,600,000	17,300,000 r/	16,300,000 r/	16,700,000 r/	17,700,000

e/ Estimated. r/ Revised. W Withheld to avoid disclosing company proprietary data; not included in total. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through August 21, 2001.

3/ In addition to the countries listed, Iran is believed to have produced ferromanganese and silicomanganese, but production figures are not reported; general informatio is inadequate for the formulation of reliable estimates of output levels. Production of ferrosilicon, manganese ferroalloys, and silicon metal began in 1996 in Saudi Arat but data for actual production were not available.

4/ To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallothermic operation is included with electric furnace production.

5/ To the extent possible, ferroalloy production of each country has been separated to show the following individual major types of ferroalloys: ferrochromium, ferrochromiumsilicon, ferromanganese, ferronickel, ferrosilicon, silicomanganese, silicon metal, and spiegeleisen. Ferroalloys other than those listed that have been identifie specifically in sources, as well as those ferroalloys not identified specifically but which definitely exclude those listed previously in this footnote, have been reported as "Other." Where one or more of the individual ferroalloys listed separately in this footnote have been inseparable from other ferroalloys owing to a nation's reporting system, deviations are indicated by individual footnotes.

6/ Includes calcium-silicon.

7/ Reported figure.

8/ Includes silicomanganese, if any.

9/ Includes high- and low-carbon ferrochromium.

10/ Includes silicospiegeleisen, if any.

11/ Includes ferrochromiumsilicon and ferronickel, if any.

12/ Hungary is believed to produce some blast furnace ferromanganese.

13/ Includes charge chrome and ferrochrome.

14/ Excludes calcium-silicon.

15/ Includes calcium-silicon, ferrocolumbium, ferromolybdenum, ferrotungsten, ferrovanadium, and other ferroalloys.

16/ Salable products from Autlán.

17/ Includes production from Bophuthatswana and net production of ferrochromiumsilicon, if any.

18/ Includes ferronickel, if any.

19/ U.S. output includes chromium metal, high- and low-carbon ferrochromium, ferrochromiumsilicon, and other chromium materials.

20/ U.S. output of ferromanganese includes manganese metal and silicomanganese.

21/ Withheld to avoid disclosing company proprietary data; included with "Other."

22/ May include ferroboron, ferrocolumbium, ferromolybdenum, ferrophosphorus, ferrotitanium, ferrotungsten, ferrovanadium, nickel columbium, and silvery pig iron.

23/ Spiegeleisen, if any, for Germany is included with blast furnace ferromanganese.

24/ Includes ferrophosphorus and data contained in "Blast furnace: Other."

25/ Ferrochromium includes ferrochromiumsilicon, if any, for Japan, South Africa, and the United States.

26/ Ferromanganese includes silicomanganese, if any, for North Korea.

27/ U.S. production is included with "Other."

28/ Includes silicospiegeleisen, if any, for France.

29/ Includes calcium-silicon, ferromolybdenum, ferrovanadium, silicomanganese for the United States, and data contained with "Electric furnace: "Other" for each country indicated.

FLUORSPAR

By M. Michael Miller

Domestic survey data and tables were prepared by Cindy Chen, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Traditionally, fluorspar has been considered to be vital to the Nation's national security and economy. It is used directly or indirectly to manufacture such products as aluminum, gasoline, insulating foams, refrigerants, steel, and uranium fuel. Most fluorspar consumption and trade involve either acid grade, which is greater than 97% calcium fluoride (CaF_2), or subacid grade, which is 97% or less CaF_2. The latter includes metallurgical and ceramic grades and is commonly called metallurgical grade.

All domestic sources of fluorspar are derived from sales of material from the national defense stockpile (NDS) and from a small amount of synthetic fluorspar produced from industrial waste streams. Byproduct fluorosilicic acid production from some phosphoric acid producers supplements fluorspar as a domestic source of fluorine, but is not included in fluorspar production or consumption calculations. According to the U.S. Census Bureau and the U.S. Geological Survey (USGS), imports of fluorspar increased by 9% compared with those of 1999. Hydrofluoric acid (HF) imports also increased by 9% when compared with those of 1999.

Legislation and Government Programs

In accordance with the Strategic and Critical Materials Stock Piling Act as amended (50 U.S.C. 98h-2), the Defense National Stockpile Center (DLA-DNSC) of the Defense Logistics Agency was authorized to sell about 54,400 metric tons (t) (60,000 short dry tons) of metallurgical-grade fluorspar during fiscal year 2000 (October 1, 1999, to September 30, 2000). During calendar year 2000, the DLA-DNSC sold about 54,400 t (60,000 short dry tons) of metallurgical grade. According to the DLA-DNSC's fiscal year 2001 (October 1, 2000, to September 30, 2001) annual materials plan, total sales of about 54,400 t (60,000 short dry tons) of metallurgical grade were authorized. See the section on stocks for unsold quantities remaining in the NDS.

Production

In 2000, there was no reported domestic mine production of fluorspar, and there is no data survey for byproduct fluorspar. Domestic production data for fluorosilicic acid were developed by the USGS from voluntary surveys of U.S. operations. Of the 11 fluorosilicic acid operations surveyed, 10 respondents reported production, and 1 respondent reported zero production, representing 100% of the quantity reported.

Hastie Mining Co. washed, screened, and dried metallurgical- and acid-grade fluorspar imported or purchased from the NDS. Seaforth Mineral & Ore Co., Inc., dried and screened imported or NDS fluorspar at its facilities at Cave-In-Rock, IL, and East Liverpool, OH, as did Applied Industrial Materials Corp. at its facility at Aurora, IN.

In 2000, 6 companies operated 10 plants that processed phosphate rock for the production of phosphoric acid, that generated 68,000 t of byproduct fluorosilicic acid. They sold or used 67,800 t of byproduct fluorosilicic acid at a value of about $10 million. This was equivalent to approximately 119,000 t of fluorspar (grading 92% CaF_2) sold or used. This was essentially unchanged from the level of fluorosilicic acid output reported in 1999. Because fluorosilicic acid is a byproduct of the

Fluorspar in the 20th Century

In 1900, U.S. fluorspar production was 16,700 metric tons, with more than 80% of it mined in Caldwell, Crittenden, and Livingston Counties in Kentucky. The remainder of the output came from the well-known mining district near Rosiclare in Hardin County, IL. Processing of the product simply consisted of washing and screening, although in 1900, two producers were building facilities to grind the fluorspar prior to sale. In 1920, the flotation process was introduced, which allowed production of fluorspar of more than 97% purity, which became known as acid-grade fluorspar. At the beginning of the 20th century small amounts of fluorspar were consumed for ceramics, enamels, foundry work, glass, hydrofluoric acid, and steel. Since the introduction of the open hearth furnace to the United States in 1888, however, the use of fluorspar as a flux in steelmaking had been increasing.

For most of the century, demand for fluorspar grew steadily, driven during the first quarter of the century almost entirely by the steel market and, from the 1930s on, by the steel market and the development of chlorofluorocarbons (CFCs), which provided a new market for hydrofluoric acid (HF). Demand peaked in 1974, when U.S. consumption reached 1.38 million metric tons, at which time about 55% of consumption was acid-grade fluorspar and 45% was metallurgical-grade fluorspar. During the last quarter of the century, fluorspar's use in steelmaking decreased dramatically, and CFC production was discontinued for environmental reasons. By the end of the century, domestic annual consumption of fluorspar had leveled off in the 500,000- to 600,000-ton range, with consumption for HF production accounting for about 80% of apparent consumption. During the 20th century, the U.S. fluorspar mining industry grew substantially and reached peak production during World War II, when shipments reached 375,000 tons in 1944. The postwar years would see the beginning of a trend of decreasing domestic production and increasing imports; by the end of the century domestic mining of fluorspar had ceased entirely.

Digitized by Google

phosphate fertilizer industry and is not manufactured for itself alone, shortages may occur when phosphate fertilizer production goes down.

Some synthetic fluorspar was recovered as a byproduct of uranium processing, petroleum alkylation, and stainless steel pickling. The majority of the marketable product was estimated to come from uranium processing. At present, an estimated 5,000 to 8,000 t of synthetic fluorspar is produced annually in the United States.

Environment

The U.S. Environmental Protection Agency (EPA) released a review draft of its report titled "Estimates of U.S. Emissions of High-Global Warming Potential Gases and the Costs of Reductions." The preliminary draft report presented current forecasts of emissions of high-global-warming-potential gases (HGWPG) in the United States and assembled the available cost and market information on the technologies that could reduce these emissions. Using this information, marginal abatement curves were generated that attempted to quantify the achievable emission reductions at increasing values for carbon. The preliminary draft was released to solicit comments and additional information on the costs of reducing emissions of the HGWPG, which include hydrofluorocarbons (HFCs), perfluorocarbons, and sulfur hexafluoride (U.S. Environmental Protection Agency, March 2000, Estimates of U.S. emissions of high-global warming potential gases and the costs of reductions, accessed July 26, 2000, at URL http://www.epa.gov/ghginfo/new.htm).

Consumption

Domestic consumption data for fluorspar were developed by the USGS from voluntary surveys of U.S. operations (table 2). The consumption survey was sent to 40 operations quarterly and to 3 small operations annually. In 2000, on average, 35 operations responded to the consumption surveys, representing 88% of those operations surveyed. These respondents accounted for 98% of the reported U.S. consumption. Estimates for nonrespondents were based on past consumption levels, trends, and nonsurvey sources. Owing to the existence of additional consumers that are not surveyed, the reported consumption figures are estimated to constitute about 87% of the actual U.S. annual consumption.

Traditionally, there have been three grades of fluorspar: acid grade, containing more than 97% CaF_2; ceramic grade, containing 85% to 95% CaF_2; and metallurgical grade, containing 60% to 85% or more CaF_2. During the past several decades, there has been a general movement toward the use of higher quality fluorspar by many of the consuming industries. For example, welding rod manufacturers may use acid-grade fluorspar rather than ceramic grade, and some steel mills use ceramic or acid grade rather than metallurgical grade. The following is a discussion of the general uses of fluorspar by grade and, in the case of acid grade, the uses of some of its important downstream products.

Acid-grade fluorspar was used primarily as a feedstock in the manufacture of HF. Two companies reported fluorspar consumption for the production of HF, E.I. du Pont de Nemours and Co., Inc. (DuPont), and Honeywell International Inc.

The largest use of HF was for the production of a wide range of fluorocarbon chemicals, including HFCs, hydrochlorofluorocarbons (HCFCs), and fluoropolymers. HCFCs and HFCs were produced by the following eight companies: ATOFINA Chemicals, Inc. (formerly Elf Atochem North America, Inc.); Ausimont USA, Inc.; DuPont; Great Lakes Chemical Corp.; Honeywell; INEOS Fluor Americas LLC (formerly I.C.I. Americas, Inc.); La Roche Chemicals, Inc.; and MDA Manufacturing Ltd. MDA is a joint venture between Daikin America Inc. and 3M Corp. to produce HCFC 22 and hexafluoropropane for captive use in fluoropolymer manufacturing.

Some of the existing or potential fluorocarbon replacements for the banned chlorofluorocarbons (CFCs) are HCFCs 22, 123, 124, 141b, 142b, and 225. These HCFC substitutes have ozone-depletion potentials that are much lower than those of CFCs 11, 12, and 113, which together had accounted for more than 90% of CFC consumption. HCFC 22 has been used as a high-pressure refrigerant (e.g., in home air conditioning) for years; HCFC 123 is being used as a replacement for CFC 11 in low-pressure centrifugal chillers; HCFC 124 is a potential replacement for CFC 114 in medium-pressure centrifugal chillers and for CFC 12 as a diluent in sterilizing gas; and HCFCs 141b and 142b have replaced most of the CFCs 11 and 12 used in foam blowing. HCFCs 141b and 225, perfluorocarbons, and hydrofluoroethers have been introduced as replacements for CFC solvents. However, because of the current phaseout schedule for HCFCs, the market for HCFCs will exist for only a short time, and perfluorocarbons are on the list of gases that contribute to global warming. Of most immediate concern is the ban on production and importation of HCFC 141b, which is scheduled to go into effect January 1, 2003.

The HFC replacements have no ozone-depletion potential because they contain no chlorine atoms. The most successful HFC replacement compound is HFC 134a. It is the main replacement for CFC 12 in automobile air conditioners and is being used as the refrigerant in new commercial chillers and refrigerators and as the propellant in aerosols and tire inflators. HFCs 23, 32, 125, 143a, and 152a also are being produced domestically but in much smaller quantities. These HFCs hold potential for use individually or, more likely, in blends for specific uses, such as the azeotropic mixture of HFCs 32 and 125 that is emerging as the replacement of choice for HCFC 22. HFCs 134a and 227ea are being evaluated for use in medical aerosols. In 2000, Great Lakes Chemical and ICI Klea (now part of INEOS Fluor) announced that they were forming a joint venture to manufacture and supply HFC 227ea for use in measured dose inhalers. The new facility will be located at Great Lakes' facility in southern Arkansas (ICI Klea, February 9, 2000, INEOS Fluor in rally across Africa, accessed February 22, 2000, at URL http://www.klea.co.uk/news/view.cfm?id=51). HFC 227 also is an alternative to CFC 114, while HFC 245ca and HFC 356 are identified as possible long-term replacements for CFC 11 in chillers and for CFC 114 in high-temperature heat pumps. HFC 245fa may be a candidate for use as a low-pressure refrigerant to replace HCFC 123.

HFCs 134a, 245fa, 356, and 365mfc are being tested as potential replacements for HCFC 141b in blowing agents for thermosets, such as polyurethane. HFC 245fa appears to be further along in its development, and Honeywell has started construction of a new facility in Geismar, LA, to produce HFC 245fa for use in a range of foam-blowing applications in rigid polyurethane and polyisocyanurate foam insulation (Chemical Market Reporter, 2000). In a competing technology, ATOFINA

Digitized by Google

announced the development of new technology to improve polyurethane foams manufactured with HFC 134a and other gaseous blowing agents. The new technology allows use of up to 75% HFC 134a while yielding foams similar to those blown with HCFC 141b. Further development and testing are required to confirm the commercial performance of the foams (ATOFINA Chemicals, Inc., January 24, 2001, ATOFINA Chemicals, Inc. announces development of improved technology for HFC-134a in insulation foam applications, accessed May 24, 2001, via URL http://www.atofinachemicals.com/whatsnew).

HFC 4310 has been developed as a replacement for CFC 113, HCFCs, and perfluorocarbons for use in drying fluids, cleaning and rinsing agents, defluxing agents, and heat-transfer media. DuPont has introduced a range of new specialty cleaning fluids for applications, including aerosol solvents, precision metal cleaning, defluxing and carrier fluids for applying lubricants. The new products are blends of HFC 4310 and HFC 365 that are stable, nonflammable, and have lower global warming potential than many previously existing products (Optical World, October 20, 2000, Cleaning fluid from DuPont, accessed June 15, 2001, at URL http://www.optical-world.co.uk/October%202000%20optiproducts.htm).

HCFCs 22, 123, and 124; HFCs 23, 125, 134a, and 227ea; and a number of other fluorine compounds have been approved by EPA as acceptable substitutes (some subject to use restrictions) for halon streaming agents for fire suppression.

CFC 113, HCFCs 22 and 142b, and HFC 152a were produced as chemical intermediates in the production of fluoropolymers. Fluoropolymers have desirable physical and chemical properties that allow them to be used in products from pipes and valves to architectural coatings to cookware. These intermediate uses of CFC 113 and HCFCs 22 and 142b will not be subject to the production phaseouts mandated by the Montreal Protocol and the Clean Air Act Amendments of 1990 because these products are consumed in the manufacturing process.

HF was consumed in the manufacture of uranium tetrafluoride, which was used in the process of concentrating uranium isotope 235 for use as nuclear fuel and in fission explosives. It also was used in stainless steel pickling, petroleum alkylation, glass etching, treatment of oil and gas wells, and as a cleaner and etcher in the electronics industry. HF was used as the feedstock in the manufacture of a group of inorganic fluorine chemicals that include chlorine trifluoride, lithium fluoride, sodium fluoride, sulfur hexafluoride, tungsten hexafluoride, and others that are used in dielectrics, metallurgy, wood preservatives, herbicides, mouthwashes, decay-preventing dentifrices, and water fluoridation.

Acid-grade fluorspar was used in the production of aluminum fluoride (AlF_3), which is the main fluorine compound used in aluminum smelting. In the Hall-Héroult aluminum process, alumina is dissolved in a bath of molten cryolite, AlF_3, and fluorspar to allow electrolytic recovery of aluminum. On average worldwide, the aluminum industry consumes about 23 kilograms of fluorides (measured as AlF_3 equivalent) for each metric ton of aluminum produced, ranging from 10 to 12 kilograms per metric ton (kg/t) in a modern prebaked aluminum smelter to 40 kg/t in an older Soderberg smelter without scrubbers. AlF_3 was added to the electrolyte in reduction cells to improve the cells' electrical efficiency. It was used by the ceramic industry for some body and glaze mixtures and in the production of specialty refractory products, and in the manufacture of aluminum silicates and in the glass industry as a filler. The AlF_3 manufactured for use in aluminum reduction cells is produced directly from acid-grade fluorspar or from byproduct fluorosilicic acid. About 82% of AlF_3 is produced from fluorspar and 18% from fluorosilicic acid (excluding China, the Commonwealth of Independent States, and Russia for which specific data are unavailable). In 2000, Alcoa World Chemicals, a business unit of Alcoa Inc., produced AlF_3 from fluorspar at Point Comfort, TX.

Ceramic-grade fluorspar was used by the ceramic industry as a flux and an opacifier in the production of flint glass, white or opal glass, and enamels. Ceramic grade was also used to make welding rod coatings and as a flux in the steel industry.

Metallurgical-grade fluorspar was used primarily as a fluxing agent by the steel industry. Fluorspar is added to the slag to make it more reactive by increasing its fluidity (by reducing its melting point) and thus increasing the chemical reactivity of the slag. Reducing the melting point of the slag brings lime and other fluxes into solution to allow the absorption of impurities. Fluorspar of different grades was used in the manufacture of aluminum, brick, cement, and glass fibers and by the foundry industry in the melt shop.

The U.S. steel industry reported high levels of production during the first half of 2000, but a slowing economy and increased imports resulted in a decrease in production of 11% in the second half. This was reflected in the industry's capacity utilization, which averaged 90% for the first half of the year but only 80% in the second half and by December had fallen to 72%. For the year, raw steel production was up by 4.2% (3.1% for basic oxygen process and 5.5% for electric arc process) compared with 1999.

The merchant-fluorspar market includes metallurgical-grade and acid-grade sales to steel mills, foundries, glass and ceramics plants, welding rod manufacturers, and other small markets in rail car, truckload, and less than truckload quantities. This merchant market is mature and in the United States amounts to about 115,000 metric tons per year (t/yr), equally divided between acid-grade and metallurgical-grade sales. Over the years, fluorspar usage in such industries as steel and glass has declined because of product substitutions or changes in industry practices.

The level of total reported fluorspar consumption was essentially unchanged in 2000 compared with that of 1999. Consumption of acid grade for HF and AlF_3 was essentially unchanged, but consumption for other uses decreased by 14%, although the data collected for non-HF/AlF_3 markets are believed to be underreported and may not accurately reflect the true size of these markets.

About 33,700 t of byproduct fluorosilicic acid valued at $4.98 million was sold for water fluoridation, about 20,400 t of fluorosilicic acid valued at $2.28 million was sold to make AlF_3 for the aluminum industry, and about 13,700 t valued at $2.78 million was sold or used for other uses, such as sodium silicofluoride production.

Stocks

Consumer stocks at yearend totaled 73,900 t, which was a decrease of 18% from 1999 levels. Consumer and distributor stocks totaled of 289,000 t, which included 215,000 t purchased from the NDS but still located at NDS depots. As of December 31, 2000, the NDS fluorspar inventory classified as excess (excluding material sold pending shipment) contained only about 112,000 t (123,000 short dry tons) of metallurgical-grade

Digitized by Google

material. About 51% of the remaining metallurgical-grade material was classified as nonstockpile grade.

Transportation

The United States is import dependent for the majority of its fluorspar supply. Fluorspar is transported to customers by truck, rail, barge, and ship. Metallurgical grade is shipped routinely as lump or gravel, with the gravel passing a 75-millimeter (mm) sieve and not more than 10% by weight passing a 9.5-mm sieve. Acid grade is shipped routinely in the form of damp filtercake containing 7% to 10% moisture to facilitate handling and to reduce dust. Most acid-grade imports come from China and South Africa. Fluorspar is shipped by ocean freight using the "tramp" market for ships. Bulk carriers of 10,000 to 50,000 t deadweight normally are used. Participants negotiate freight levels, terms, and conditions.

Prices

According to Industrial Minerals magazine (London), yearend price ranges for Mexican fluorspar, free on board (f.o.b.) Tampico, were unchanged at $110 to $130 per metric ton for acid grade and $85 to $105 per ton for metallurgical grade, but increased to $132 to $145 per ton for low-arsenic acid grade (table 3). The range of South African prices for acid grade, f.o.b. Durban, remained unchanged at $105 to $125 per ton. No specific prices were available for Chinese fluorspar. According to Industrial Minerals magazine, the average U.S. Gulf port price, including cost, insurance and freight (c.i.f.), dry basis, for acid grade was $130 to $135 per ton. This would be the average delivered price of Chinese, Mexican, and South African acid grade at Gulf ports.

Prices of imported acid-grade fluorspar during the past 10 years have exhibited a roller-coaster pattern of highs and lows (figure 1). Prices have been affected by major factors, such as the severe drop in demand caused by the CFC phaseout, major increases in Chinese exports and the resulting cutthroat competition between Chinese exporters, and the introduction of Chinese export quotas and license fees. Lesser factors that affected prices were sales from the NDS and variations in shipping rates.

According to Chemical Market Reporter, the yearend 2000 price quotation for aqueous HF, 70%, in drums, f.o.b., freight allowed, was unchanged at $0.65 per pound. The quotation for chemically pure (99.0 weight percent) anhydrous HF, 1,300 pounds, f.o.b., was unchanged at $2.96 per pound. Quoted yearend prices for AlF_3 ranged from $825 to $1,408 per metric ton. Quoted prices for sodium fluoride, white, 97%, in 50- or 100-pound bags, drums, carloads, f.o.b. Tampa, was $0.60 per pound, and $0.63 per pound at El Paso. A price quote for fluorosilicic acid was unavailable.

Foreign Trade

According to the U.S. Census Bureau, U.S. exports of fluorspar decreased by 28% to 39,800 t from the 1999 figure (table 4). All U.S. exports were believed to be reexports of material imported into the United States or exports of material purchased from the NDS.

In 2000, imports for consumption of fluorspar increased by 9% when compared with those of 1999, according to the U.S. Census Bureau and USGS data (table 5). The largest suppliers of fluorspar to the United States were, in descending order, China, South Africa, and Mexico. China accounted for nearly 63% of U.S. fluorspar imports. The average c.i.f. unit value, in dollars per metric ton, was $128 for acid grade and $84 for metallurgical grade.

There are no tariffs on acid-grade or subacid-grade (metallurgical-grade) fluorspar from normal-trade-relations countries. There are no tariffs on other major fluoride minerals and chemicals, such as natural or synthetic cryolite, hydrofluoric acid, and aluminum fluoride.

Imports of HF increased by 9% to 131,000 t, or a quantity equivalent to about 196,000 t of fluorspar (table 6). Imports of synthetic and natural cryolite decreased by nearly 4% to 9,190 t, or a quantity equivalent to approximately 11,000 t of fluorspar (table 7). Imports of AlF_3 increased by 11% to 21,500 t, or a quantity equivalent to about 32,200 t of fluorspar (table 8).

World Review

World production increased by nearly 100,000 t compared with the revised 1999 data (table 9). Mexico (13%) and Mongolia (29%) reported the largest increases.

Canada.—In 2000, Canada imported 19,300 t of metallurgical-grade fluorspar and 161,000 t of acid-grade fluorspar. Total fluorspar imports increased by 6% compared to those of 1999. The major sources of supply were, in descending order, Mexico, Morocco, and China (Jane Currie, Minerals and Mining Statistics Division, Natural Resources Canada, written commun., 2001). The two major fluorspar consumers in Canada are the Honeywell HF plant at Amherstburg, Ontario, and Alcan Aluminium Ltd., which produces AlF_3 at its Vaudreuil refinery at Jonquière, Québec.

The previously announced merger between Canadian companies Burin Fluorspar Ltd. and Blue Desert Mining Inc. was unsuccessful. Shareholders had apparently approved the merger but delays in acquiring regulatory approval and the soft mining sector were given as reasons for the failure. Blue Desert had changed its name to Canada Fluorspar Inc. in anticipation of the expected merger, but Burin Fluorspar and Canada Fluorspar are in no way affiliated. Burin Fluorspar continued its attempts to arrange financing to reopen the mine and mill at St. Lawrence, Newfoundland, and to find a strategic joint-venture partner to take partial ownership in the company (Burin Minerals Ltd., 2000).

China.—Determining China's actual production data for acid- and metallurgical-grade fluorspar has always been difficult owing to the lack of official Government data and the complex nature of the network of producers, processors, exporters, and consumers in China. Problems range from an unreliable breakdown of export data by grade to the lack of reliable information on domestic consumption levels, which may include more than 400,000 t/yr of submetallurgical-grade fluorspar for cement and glass manufacturing.

Although China's fluorspar production and export levels have remained fairly constant, there have been numerous plant and mine closures, openings, and consolidations in recent years resulting in the number of active mills decreasing to about 80 in 2000 from about 125 in 1997. As a result, the distribution of production across China has changed. Zhejiang Province continues to be a major producing area, but smaller producing provinces such as Hubei and Shandong have seen capacity plummet, while the southern provinces of Jujian and Jiangxi have reported dramatic increases in production (Industrial

Digitized by Google

Minerals, 2001).

In late 2000, the Chinese Ministry of Foreign Trade and Economic Cooperation held bidding for about 750,000 t of an expected total of 1.15 Mt of fluorspar authorized for export in 2001. There was about 395,000 t released under agreement bids at $39 per ton and 350,000 t under open bid at about $84 per ton. This averaged to about $60 per ton, which was $15 per ton higher than the average in 2000.

European Union.—After a review of the antidumping duties (established in December 1995) on imports of Chinese fluorspar in the form of filtercake or powder into the European Union (EU), the Council of the European Union determined that the duty should be maintained. The duty remains equal to the difference between a minimum price of 113.5 euros per dry ton and the net, free-at-Community-frontier price, before customs clearance (Industrial Minerals, 2000b).

After a 4-month series of conciliation talks between members of the European Parliament and EU Governments, a new timetable for the phaseout of HCFCs in the EU was approved. HCFCs may not be used in new refrigeration equipment after July 1, 2002, and after 2010, virgin HCFCs may not be used, even in existing refrigeration and air-conditioning equipment. Recycled HCFCs may be still be used as an alternative to virgin material from 2010 to 2015, at which time a total ban goes into effect (European Chemical News, 2000).

France.—The merger of Elf Aquitaine S.A. and TotalFina S.A., France's largest oil and gas companies, into the newly-merged group TotalFinaElf S.A., resulted in the reorganization of all chemical activities under the name ATOFINA S.A. Elf Atochem North America, Inc., a major producer of fluorochemicals for the foam blowing and refrigeration markets, was renamed ATOFINA Chemicals, Inc. The company will remain headquartered in Philadelphia, PA (ATOFINA Chemicals, Inc., June 19, 2000, Letter to customers—Elf Atochem North America, Inc., now ATOFINA Chemicals, Inc., accessed July 30, 2000, via URL http://www.atofinachemicals.com/whatsnew/index.cfm?DisplayDate=01/01/2000).

Iran.—Iran first produced fluorspar in 1960 as a byproduct of lead mining, and the first fluorspar mine was developed in 1968. In 2000, there were reportedly 10 active mines, most of which are small and produce only a few thousand tons per year. The largest by far is the Kamar Mehdi Mine, which produces about 20,000 t/yr and is located 165 kilometers southwest of Tabas in Khorassan Province. All of Iran's production is metallurgical grade, much of which is hand sorted, although mechanical sorting is used at Kamar Mehdi on smaller size material. The USGS estimated Iran's 2000 production at 20,000 t, but it may be as high as 40,000 to 50,000 t (Hadavi, 2001).

Mexico.—DuPont announced plans to sell its 32.88% stake in Mexican HF producer Quimica Fluor S.A. de C.V. to Inmuebles Cantabria S.A. de C.V. Quimica Fluor operates at Matamoros, just across the border from Brownsville, TX. The Quimica Fluor plant has a capacity of 86,000 t/yr and produced about 77,000 t of HF in 1999. DuPont had been a shareholder since 1971, but management no longer believed that maintaining an equity interest in Quimica Fluor was necessary to meet its business needs (Industrial Minerals, 2000a).

The Solvay Group, based in Belgium, acquired Mexican HF producer Norfluor S.A. Norfluor manufactures hydrofluoric acid, ammonium fluoride, and ammonium bifluoride at its plant in Ciudad Juárez. The plant's HF capacity is 31,000 t/yr. To reflect the new ownership of the plant, Norfluor's name was changed to Solvay Fluor México, S.A. de C.V. (Industrial Minerals, 2000c).

Russia.—In late 1999, the Government increased import duties on fluorspar to 15% from 5% to make market conditions more favorable to Russian producers. In 2000, however, the largest domestic producer, Yaroslavsky Mining & Dressing Complex (YMDC), reportedly intended to ask the Russian Government to prohibit tenders on delivering foreign fluorspar to Russia. In lieu of this, YMDC believed that the duties should be raised to 30%. In 2000, YMDC increased its production to about 160,000 t (Industrial Minerals, 2000d).

South Africa.—The Buffalo fluorspar mine in South Africa, which shut down in early 1994, was acquired in May 2000 by International Metals Processing (Pty.) Ltd. (IMP). The company overhauled and recommissioned the flotation plant and associated equipment, a project that was completed by the end of October 2000. The company stated that initially they would be processing feed from high-grade stockpiles and tailings dumps. They planned to recommission the briquet plant to process any material that failed to meet the acid-grade standards. Restarting full-scale mining is not expected until 2003, at which time the mine would have reserves sufficient to maintain mine production for 15 years. Sales in the fourth quarter of 2000 were limited and on a spot basis, but IMP worked on marketing its product directly to consumers worldwide (International Metals Processing (Pty.) Ltd., 2000). The product may be excluded from some acid-grade markets, however, because of high phosphorus levels.

When the Buffalo fluorspar mine was closed by General Mining Union Corp. (GENCOR) in 1994, the company gave as the reasons lower world demand and a drop in prices. In GENCOR's opinion these made the mine unprofitable. This was when Chinese acid-grade prices were $65 to $70 per ton, f.o.b. China, or about $95 per ton U.S. Gulf coast. Under these conditions, GENCOR stated they only had 2 years of reserves left. Because the definition of reserves has an economic dimension, fluorspar prices have an effect on reserve estimates. Reserves as measured at a delivered price of $95 per ton would be lower than those measured at $120 per ton.

Vergenoeg Mining Co. (Pty.) Ltd. got approval for its environmental management plan (EMP) from the Department of Minerals and Energy. The EMP considered premining land use, the effect on the environment during mining, the anticipated postmining land use, and the socioeconomic effect of the employment of the local population. After the acquisition of the mine in 1999, partners Metorex (Pty.) Ltd. and Minerales y Productos Derivados S.A. completed a computer model of the ore body; evaluated the existing plant configuration, available equipment, and processing methods; and decided to proceed with long-term capital investment to improve quality and recovery at the mine (Cooke, 2001).

Current Research and Technology

Representatives of Italian fluorochemicals producer Fluorsid S.p.A. and Swedish process equipment manufacturer Svedala Ltd. presented a paper entitled "Recovery of Fluosilicic Acid and Fluoride Bearing Waters for the Production of a Mixture of Silica and Precipitated Calcium Fluoride Usable for the Production of Cement" at the International Fertilizer Industry Association's 2000 Technical Conference in New Orleans. The process, which has been used by Fluorsid for 9 years, involves the treatment of process waters containing HF, H_2SiF_6, HCl, and H_2SO_4 via water treatment and filtration. The process waters

Digitized by Google

are initially treated with limestone and then with hydrated lime (calcium hydroxide). A flocculating agent is added, the slurry is clarified, and then sent to a thickener to bring it up to the optimum concentration for filtration (280 to 300 grams per liter). The slurry is pumped into Svedala tube presses, which, under 100-bar pressures, filter out the solids that are discharged in hard, compact flakes 1 to 3 centimeters thick. The product has a composition of CaF_2 (50% to 65%), SiO_2 (9% to 10%), $CaSO_4$ (8% to 10%), $CaCO_3$ (3% to 6%), Al_2O_3 (2% to 3%), Fe_2O_3 (1% to 2%), and $MgCO_3$ (1% to 2%). This product has been found suitable for use in cement manufacturing where a small amount of low-grade fluorspar is added as a flux to reduce the residence time of raw materials in the kiln and thus increase production capacity.

This process was tested to determine its applicability for use in processing fluorosilicic acid from phosphoric acidplants. The tests returned results of CaF_2 (70%), SiO_2 (17%), $CaCO_3$ (6%), Al_2O_3 (1%), and Fe_2O_3 (1%). Although still suitable for the cement market, the high SiO_2 content would likely make it unsuitable for the metallurgical market. Fluorsid believes that the process could be successfully applied to fluorinated muds produced from the processing of phosphate rock (Lavanga and others, 2000).

Outlook

Fluorocarbon production from HF is the single largest market that drives fluorspar demand. Demand for HFC 134 is benefiting from steady auto sales, retrofits, and an emerging aftermarket. In the United States, HFCs and HCFCs used as refrigerants in large cooling chillers are in demand as the conversion from CFC chillers to non-CFC chillers continues. Chillers cool water that is circulated through buildings to air condition factories, hospitals, malls, offices, etc. By the end of 2001, it was expected that about one-half of the 80,000 CFC chillers in operation in the early 1990s would have been converted. The rate of conversion will likely be accelerated because of high electricity prices (new chillers can be 40% more efficient than the units being replaced) and a shrinking supply of CFCs 11 and 12. As an indication of the expected increase in demand, companies have completed or announced capacity increases for HFCs 32, 125, 134a, 227ea, and 245fa in France, Germany, Japan, the United Kingdom, and the United States. There is, however, much uncertainly related to market losses to not-in-kind replacements, tighter recycling requirements in air-conditioning systems that will reduce aftermarket sales, the ban on the foam-blowing agent HCFC 141b in 2003, and potential future restrictions owing to the global warming potential of fluorocarbons. The fluoropolymer and fluoroelastomer markets are growing at an even faster rate, and fluorine compounds such as chlorine trifluoride, nitrogen trifluoride, and tungsten hexafluoride used by the semiconductor industry are in increased demand.

In recent years, the aluminum industry has experienced a 3.3% annual decrease in the consumption of AlF_3. This was the result of better filtering of alumina hydrate to remove Na_2O, an impurity the addition of AlF_3 addresses, and because the new smelters introduced had much lower AlF_3 consumption rates. This trend is expected to reverse itself, especially since the largest increases in aluminum production are expected to be in China and the Commonwealth of Independent States (C.I.S.), which will continue using older smelters. Considering only that portion of AlF_3 demand supplied by fluorspar, based on estimates of relative aluminum production growth for China, C.I.S, and the West, the demand for fluorspar in this market may increase by as much as 15,000 to 17,000 t/yr through 2004. The largest portion of this increase is expected to occur in China and the C.I.S. In the longer term, new smelting technologies could lower fluorspar demand significantly. Widespread adoption of the new Kvaerner Process Technology fluorosilicic acid/HF process, which can be used to manufacture AlF_3 as a byproduct of phosphoric acid production, could conceivably replace the production of AlF_3 from fluorspar (Reynolds, 2001).

The domestic steel industry is plagued by high levels of imports, large inventories, and bankruptcies; the slowing economy will only exacerbate the industry's problems. Through the middle of June 2001, domestic steel production was 13% lower than that in the same period in 2000. These factors are expected to cause an estimated 10% decrease in U.S. steel production in 2001, and fluorspar sales for steel are likely to decrease by a similar amount. The economic slowdown will have a similar effect, although probably not as large, on other small merchant markets. In the long term, growth is still expected in the cement market. Some cement manufacturers are starting to use fluorspar in clinker production. Fluorspar can be added to limestone in the cement kiln as a fluxing agent, where it reduces the residence time and increases production capacity.

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through June 1, 2001.

3/ In addition to the countries listed, Bulgaria is believed to have produced fluorspar in the past, but production is not officially reported, and available information is inadequate for the formulation of reliable estimates of output levels.

4/ An effort has been made to subdivide production of all countries by grade (acid, ceramic, and metallurgical). Where this information is not available in official reports of the subject country, the data have been entered without qualifying notes.

5/ Includes submetallurgical-grade fluorspar used primarily in cement that may account for 33% to 50% of the quantity.

6/ Reported figure.

7/ Year beginning March 21 of that stated.

8/ Data are reported by Consejo de Recursos Minerales, but the production of submetallurgical and acid grades has been redistributed on the basis of industry data.

9/ Principally submetallurgical-grade material.

10/ Data are in wet tons.

11/ Based on data from the South African Minerals Bureau, data show estimated proportions of acid-, ceramic-, and metallurgical-grade fluorspar within the reported totals.

GALLIUM

By Deborah A. Kramer

Domestic survey data and tables were prepared by Carolyn F. Crews, statistical assistant.

By yearend, worldwide gallium supplies were insufficient to meet consumption rates. Free market gallium prices skyrocketed to reach $1,500 to $2,000 per kilogram, a level not seen since the early 1960s when technologic improvements in gallium recovery processes brought down the price from $3,000 per kilogram.

Gallium demand in the United States was met by imports, primarily high-purity material from France and low-purity material from Kazakhstan. More than 95% of the gallium consumed in the United States was in the form of gallium arsenide (GaAs). Analog integrated circuits (ICs) were the largest application for gallium, with optoelectronic devices [mostly laser diodes and light-emitting diodes (LEDs)] as the second largest end use. U.S. GaAs manufacturers completed many of their capacity expansions that had been announced earlier and continued planning additional capacity expansions. Many of these expansions involved conversions from 4-inch wafer processing capacity to 6-inch capability, which is considered the next plateau in GaAs processing ability. Growth in the wireless communications industry was cited as the principal driving force behind most of the GaAs production expansions.

World production of virgin gallium was estimated to be 90 metric tons (t). Total demand for refined gallium, however, was estimated to be 120 t and was centered in Japan, the United States, and Western Europe. Significant quantities of new scrap were recycled and supplemented supplies, particularly in Japan.

Production

No domestic production of primary gallium was reported in 2000 (table 1). Eagle-Picher Industries Inc. recovered and refined gallium from domestic and imported sources at its plant in Quapaw, OK. Recapture Metals Inc. in Blanding, UT, recovered gallium from scrap materials, predominantly those generated during the production of GaAs. Recapture Metals facilities have the capability to process about 17 metric tons per year (t/yr) of high-purity gallium. The company recovered gallium from its customers' scrap on a fee basis and purchased scrap and low-purity gallium for processing into high-purity material.

Consumption

More than 95% of the gallium consumed in the United States was in the form of GaAs. GaAs was manufactured into optoelectronic devices (LEDs, laser diodes, photodetectors, and solar cells) and ICs. Analog ICs were the largest end-use application for gallium, with 63% of total consumption. Optoelectronic devices accounted for 32% of domestic consumption, and the remaining 5% was used in digital ICs, research and development, and other applications (tables 2, 3).

Gallium consumption data are collected by the U.S. Geological Survey from one voluntary survey of U.S. operations. In 2000, there were 13 responses to the consumption of gallium survey, representing 59% of the total canvassed. Because of the poor response rate, data in tables 2 and 3 were adjusted by incorporating estimates to reflect full industry coverage.

Projected growth in GaAs components for wireless applications led to the completion of several new GaAs manufacturing facilities and announcements of more expansions. In 2000, M/A-Com Inc., Lowell, MA, completed an expansion of its GaAs wafer fabrication capacity, adding a new high-volume 6-inch wafer manufacturing line. The expansion resulted from a multiyear agreement with Sanders Corp., based in Nashua, NH, in which M/A-Com will use existing capacity and equipment at the Sanders facility to

Gallium in the 20th Century

Although gallium had been discovered in 1875, it was not produced in the United States until 1915, and commercial-scale recovery did not begin until 1943. Until 1960, gallium had very limited uses. Most of its consumption was for experimental purposes; small quantities were used as a specialized mirror coating, in high-temperature thermometers, and in low-melting-point metal alloys. Although few statistical data are available, U.S. demand for gallium was considered negligible (fewer than 50 kilograms) until 1965. Introduction of the gallium-arsenide-based light-emitting diode (LED) changed the consumption pattern of gallium from that of a laboratory curiosity to a metal with some consumer applications. LEDs, used in such applications as displays in digital watches and hand-held calculators, were responsible for large annual increases in consumption from the mid-1960s until the mid-1970s. Gallium consumption continued to grow throughout the remainder of the century as new uses were developed.

By 2000, the consumption of gallium in the United States had reached nearly 40 metric tons. Almost all of this was for gallium arsenide components in electronic applications. LEDs remained in widespread use for many electronic displays, including window brake lights in automobiles. Gallium-arsenide-based laser diodes were used in such items as CD and DVD players, and gallium-arsenide-based integrated circuits were used in sophisticated military radars. Scientists continue to investigate gallium's properties, which may lead to the development of new applications for gallium. As a result, growth in gallium consumption was expected to continue well into the 21st century.

Digitized by Google

manufacture monolithic microwave integrated circuits (MMICs) on 6-inch GaAs wafers for wireless and telecommunications markets. Sanders will continue to manufacture MMICs at the same facility for aerospace and defense applications. The new manufacturing line is expected to be operational by the first half of 2001 (GaAsNet, June 8, 2000, M/A-Com doubles GaAs fab capacity, adds six-inch wafer line, accessed June 9, 2000, at URL http://www.gaasnet.com/news/macom_08062000.html). In March, M/A-Com completed the acquisition of the GaAsTEK subsidiary of ITT Corp., Roanoke, VA, which manufactures GaAs MMICs for defense industries (M/A-Com Inc., March 7, 2000, M/A-Com completes GaAsTEK acquisition, accessed March 30, 2000, at URL http://www.macom.com/about/press.asp?ID=35). This acquisition, along with the use of the Sanders facilities, gives M/A-Com four GaAs manufacturing facilities in the United States—Colorado Springs, CO; Lowell, MA; Nashua, NH; and Roanoke, VA.

In March, EMCORE Corp. completed the first phase of an expansion at its Somerset, NJ, GaAs manufacturing facility to meet increased demand for the company's heterojunction bipolar transistor (HBT) and pseudomorphic high-electron-mobility transistor (pHEMT) products; this phase doubled the company's capabilities to produce 4- and 6-inch wafers. In August, EMCORE completed a second expansion that again doubled its GaAs wafer production capacity. The first phase of the expansion added 186 square meters (m^2) of production space, which accommodated six additional epitaxial production machines. The second phase, consisting of 650 m^2, will accommodate 10 metal-organic chemical vapor deposition (MOCVD) production tools, to bring the total to 18, allowing a total annual production capacity of 360,000 6-inch wafers (EMCORE Corp., March 2, 2000, EMCORE nearly doubles production capacity for GaInP HBTs and pHEMTs to meet wireless and fiber optic market demands, accessed November 30, 2000, at URL http://www.emcore.com/html_documents/News_clips/2000/doubles_capacity.htm; GaAsNet, August 2, 2000, EMCORE completes expansion of NJ manufacturing facility, increasing capacity by 400%, accessed August 9, 2000, at URL http://www.gaasnet.com/news/emcore_02082000.html). The company also plans to triple production capacity at its EMCORE West site in Albuquerque, NM, that houses its solar cell, optical component, and networking products. The expansion will add 3,300 m^2 of capacity to the existing 4,640-m^2 facility. Completion was scheduled for yearend 2000 (GaAsNet, June 8, 2000, EMCORE plans to significantly expand Sandia Technology Park site, accessed June 9, 2000, at URL http://www.gaasnet.com/news/emcore_08062000.html).

In October, Kopin Corp. completed a 5,500-m^2 facility near its headquarters in Taunton, MA, that is expected to generate about 40% of the company's GaAs HBT business. The new facility was expected to be operational by the first quarter of 2001. As part of the expansion, Kopin ordered six HBT systems from AIXTRON AG to be delivered in the first quarter of 2001. After delivery of the new systems, Kopin will have a total of 22 machines—8 capable of handling multiple 4-inch HBTs and 14 that can handle 6-inch HBTs. Total annual production capacity will be more than 400,000 4-inch and 200,000 6-inch wafers (GaAsNet, May 16, 2000, Kopin establishes second site for HBT production, accessed June 9, 2000, at URL http://www.gaasnet.com/news/kopin_16052000.html; GaAsNet, June 11, 2000, Kopin Corporation orders six additional HBT systems from AIXTRON, accessed June 21, 2000, at URL http://www.gaasnet.com/news/kopin_11062000.html). Also in October, Kopin acquired privately held Super Epitaxial Products Inc., which conducted research and development on optoelectronic materials. Kopin believes that the acquired mix of products, combined with its technical expertise, will allow the company to provide components for existing and emerging optical communications applications. Under the terms of the agreement, 1.7 million shares of Kopin stock with an estimated value of $25 million were exchanged for all of the outstanding shares of Super Epitaxial Products (GaAsNet, October 31, 2000, Kopin acquires Super Epitaxial Products to add opto wafers, accessed October 31, 2000, at URL http://www.gaasnet.com/news/kopin_31102000.html).

ATMI Inc. (formerly Epitronics Corp.) planned to increase production capacity at its Phoenix, AZ, facility by constructing a 4,640-m^2 facility that will contain 11 AIXTRON metal-organic vapor phase epitaxy (MOVPE) reactors and will have space for 8 more. The expansion is in response to growing wireless telecommunications applications. In addition, ATMI is expanding its development of gallium nitride (GaN) wafers for blue laser diodes. The company has developed and patented a process for growing high-purity GaN wafers 50 millimeters (mm) in diameter and, based on this success, has been awarded a U.S. defense industry contract to develop the GaN wafer production capabilities further (GaAsNet, October 23, 2000, A T M I announces major HBT capacity expansion, accessed October 31, 2000, at URL http://www.gaasnet.com/news/ATMI_23102000.html).

In September, TriQuint Semiconductor Inc. purchased a wafer fabrication facility in Richardson, TX, from Micron Technology LLC for $87 million. The new facility will allow TriQuint to relocate its current Texas operation from leased space within 2 years. The company planned to install new 6-inch wafer fabrication lines that would duplicate the ones in its Hillsboro, OR, facility first, then relocate its Texas operations to the new facility. By the time the new installation, relocation, and reconfiguration are complete, the new facility will have greater capacity than the company's combined Texas and Oregon capacity (GaAsNet, September 6, 2000, TriQuint Semiconductor completes purchase of Richardson fabrication facility, accessed September 21, 2000, at URL http://www.gaasnet.com/news/triquint_06092000.html).

Sumitomo Electric Industries Ltd. announced that it would construct its first U.S. plant to produce semiconductor materials. The new plant, which will be sited in Hillsboro, OR, will initially focus on GaAs wafers for the wireless communications market and have a production volume of 20,000 wafers per month by 2002. A U.S. location would allow Sumitomo Electric Industries to meet the needs of some of its larger customers in the Western United States, such as TriQuint, TRW Inc., and Motorola Inc; 50% of Sumitomo Electric Industries' market was estimated to be in North America. The new facility also will serve as the company's U.S. headquarters. A new 12,000-m^2 GaAs production plant in Kobe, Japan, which was scheduled to be completed by July 2001, will supply 5-inch wafers to the new U.S. plant (Paul Kallender, Electronic Engineering Times, December 19, 2000, Sumitomo adds U.S. fab to GaAs expansion plans, accessed April 6, 2001, at URL http://www.eetasia.com/ART_8800066750_499481,590626.HTM).

AXT Inc. (formerly American Xtal Technology Inc.) announced that it would triple its GaAs substrate production

Digitized by Google

capacity by the end of the third quarter of 2001. Most of the expansion will be in Beijing, China, where the company operates a 5,750-m^2 facility for GaAs production and has purchased a 3,340-m^2 building adjacent to this facility. If AXT can acquire additional nearby buildings, it plans to increase its total capacity to 14,800 m^2. AXT also planned a 1,850-m^2 expansion at its Fremont, CA, plant in 2001 (AXT Inc., May 3, 2000, American Xtal Technology announces a 3x expansion of its GaAs substrate capacity by Q301, accessed February 8, 2001, at URL http://www.axt.com/050300.htm). The company also planned to discontinue its laser diode and consumer product lines in 2001 to concentrate on its core products—high-brightness LEDs and vertical cavity surface-emitting lasers (VCSELs).

ANADIGICS Inc. planned to add cleanroom space and equipment to nearly double its 6-inch indium gallium phosphide (InGaP) HBT, pHEMT, and metal semiconductor field effect transistor (MESFET) production capability. The $10 million expansion, which began in response to an increased demand for the company's wireless and broadband communications products, would link directly with ANADIGICS' existing production line at its Warren, NJ, facility. The completion was scheduled for the beginning of 2001 (GaAsNet, January 16, 2000, ANADIGICS announces plans to expand 6-inch manufacturing operation, accessed January 21, 2000, at URL http://www.gaasnet.com/news/anadigics_16012000.html).

Agilent Technologies Inc. planned to construct a new 6-inch GaAs wafer fabrication facility in Ft. Collins, CO, to produce enhancement-mode pHEMTs for handsets for mobile phones. The first phase of the project, which was scheduled to be completed by the end of 2002, will include 1,400 m^2 of cleanroom that can process 48,000 6-inch wafers per year. Until the new facility is completed, Agilent plans to produce the devices in its existing Santa Clara, CA, facility (Agilent Technologies Inc., October 18, 2000, Agilent Technologies plans six-inch wafer production fab for breakthrough E-pHEMT process, accessed November 30, 2000, at URL http://www.agilent.com/about/newsroom/presrel/2000/18oct2000a.html). Agilent ordered three molecular beam epitaxy (MBE) systems from Thermo VG Semicon Ltd. for its new facility.

Conexant Systems Inc. completed an expansion of its GaAs manufacturing facilities in Newbury Park, CA, in April. Conexant invested $80 million in capital equipment to increase its annual capacity to 95,000 4-inch wafer starts from 15,000. The new manufacturing facilities can be upgraded to 6-inch wafer capability; this conversion will increase capacity to the equivalent of 210,000 4-inch wafer starts per year. Conexant planned to use most of its expanded capacity to manufacture GaAs HBT amplifiers for the digital cellular handset market, and a small portion would be used to manufacture GaAs-HBT-based transceivers for optical communications (Conexant Systems Inc., April 10, 2000, Conexant increases manufacturing capacity five-fold for wireless communications and optical networking products, accessed April 25, 2000, via URL http://www.conexant.com).

Motorola tripled the capacity of its GaAs wafer fabrication facility in June by converting from 4-inch to 6-inch wafer capabilities and equipping the facility to its fullest capacity. The company also purchased MOCVD equipment from EMCORE for the expanded facility. This is one of the first facilities to be fully converted to 6-inch wafer capability for all GaAs technologies—MESFETs, pHEMTs, and HBTs (GaAsNet, June 16, 2000, Motorola Semiconductor completes six-inch conversion of GaAs fab three months ahead of schedule, accessed June 21, 2000, at URL http://www.gaasnet.com/news/motorola_16062000.html).

Intelligent Epitaxy Technology, Inc. (IntelliEPI), Richardson, TX, announced that it had raised $25 million in funding, which would be used to expand its production capacity. IntelliEPI planned to acquire 2,040 m^2 of additional cleanroom space and purchase four additional 6-inch multiwafer MBE systems (GaAsNet, October 14, 2000, Intelligent Epitaxy Technology, Inc. successfully raises $25 million, accessed October 31, 2000, at URL http://www.gaasnet.com/news/ie_13102000.html).

TECSTAR Inc., a Newport Beach, CA, manufacturer of solar cells, announced the formation of a new optoelectronics products organization to meet the growing demand for epitaxial wafers used in high-brightness LEDs and related optoelectronics devices. TECSTAR operated a GaAs MOCVD foundry at its Applied Solar Division. This division's facilities became available in the first quarter of 2000 to support manufacturers of high- and ultrahigh-brightness LED devices and lamps (Compound Semiconductor, January 13, 2000, TECSTAR announces formation of new optoelectronics product group, accessed April 10, 2001, via URL http://www.compoundsemiconductor.net). One of the companies that signed a long-term supply agreement with TECSTAR for use of its MOCVD production capacity was Advanced Photonics Ltd. of Shanghai, China.

TRW signed an agreement with Endgate Corp. to merge its subsidiary TRW Milliwave Inc. and create a new company, Endwave Corp. TRW manufactures transceiver modules that use GaAs MMICs for broadband systems, and Endgate manufactures transceivers, antennas, and outdoor units that enable high-speed wireless telecommunications links. The combination of these two entities into one single company will vertically integrate the production of the devices and include a long-term GaAs supply agreement with TRW. After the merger was completed, Endwave was owned about 53% by TRW and 47% by Endgate. The new firm will be headquartered in Sunnyvale, CA, and will maintain manufacturing and design facilities in Sunnyvale, Santa Clara, and Diamond Springs, CA. In July, Endwave filed an initial public offering to raise $115 million to be used for general corporate purposes and working capital (GaAsNet, March 14, 2000, TRW and Endgate announce merger forming Endwave Corporation, accessed March 14, 2000, at URL http://www.gaasnet.com/news/trw_05032000.html; GaAsNet, July 16, 2000, Radio frequency products firm Endwave files IPO, accessed August 9, 2000, at URL http://www.gaasnet.com/news/endwave_16072000.html).

Prices

In 2000, producer-quoted prices for high-purity gallium were the same as those at yearend 1999 (table 4). Quoted prices, however, do not reflect the actual price trends that occurred during the year. According to Mining Journal, prices remained relatively stable during the first three-quarters of the year, with prices for 99.9999%-pure to 99.99999%-pure material remaining at $500 to $600 per kilogram (Mining Journal, 2000). With a severe shortage of supply in the latter part of 2000, free market prices for gallium skyrocketed, with price levels of up to $1,500 per kilogram being reported by yearend (Mining Journal, 2001).

Digitized by Google

Foreign Trade

U.S. gallium imports increased by 64% from those in 1999 (table 5). France (63%), Kazakhstan (12%), Russia (5%), and the United Kingdom (5%) were the principal sources of imported gallium. In addition to gallium metal, GaAs wafers were imported into the United States. In 2000, 31,500 kilograms (kg) of undoped GaAs wafers was imported, an increase of 47% from that in 1999. Lebanon (59%) and Japan (40%) were the principal sources. [Material identified as shipped from Lebanon probably was transshipped, and the country of origin is misidentified, because Lebanon does not produce GaAs wafers.] Japan (31%), the Republic of Korea (21%), and Taiwan (15%) were the main import sources for doped GaAs wafers, totaling 296,000 kg during the year, a decrease of 5% from that in 1999. Quantities of GaAs wafers reported by the U.S. Census Bureau may include the weight of the packaging material and thus may be overstated.

World Review

Estimated crude gallium production was 90 t in 2000. Principal world producers were Germany, Japan, Kazakhstan, and Russia. China, Hungary, Slovakia, and Ukraine also recovered gallium. Refined gallium production was estimated to be about 120 t; this included some new scrap refining. France was the largest producer of refined gallium using gallium produced in Germany as feed material. Japan and the United States also refined gallium. Gallium was recycled from new scrap in Germany, Japan, the United Kingdom, and the United States.

World demand for gallium was forecast to be 210 t in 2000 by Dowa Mining Co. Ltd.; this figure included significant quantities of recycled gallium scrap. Regional demand was estimated to be as follows: Japan, 140 t; the United States, 49 t; Europe, 13 t; and other countries, 8 t. Dowa Mining projected that demand in 2001 would increase to 243 t (Roskill's Letter from Japan, 2001).

Strategies Unlimited estimated that the world market for compound semiconductors (mostly based on GaAs components) reached $18 billion in 2000, an increase of 60% from that in 1999. Optoelectronics had the largest share of the compound semiconductor market, with 80% of the total. Of the optoelectronics market, 60% was for communications applications, 16% for lamps and displays, and 24% for other applications (Hausken, 2001).

China.—The Institute of Semiconductors, which was a part of the Chinese Academy of Sciences, and four other companies signed an agreement in September to commercialize the Institute's semi-insulating GaAs technology. Under the agreement, Compound Crystal Technology Co. Ltd. would be set up by the five entities with capitalization of 100 million yuan (Y) (about $12 million), including technology valued at Y30 million (about $3.6 million). The five entities planned to invest Y300 million to Y400 million (about $36 million to $48 million) in importing production equipment and building a plant. The planned plant, the only one of its kind in China, was expected to produce single-crystal and epitaxial wafers of semi-insulating GaAs (Compound Semiconductor, September 5, 2000, Chinese firms establish venture to commercialize GaAs technology, accessed April 9, 2001, via URL http://www.compoundsemiconductor.net).

France.—Picogiga SA announced that it would double its capacity to produce epitaxial wafers at its Courtaboeuf plant by 2001. The company ordered three MBE reactors from Riber S.A. in July, two MBE reactors from Thermo VG Semicon in September, and three MBE reactors from Applied Epi Inc. in November. Five of the new reactors can process seven 6-inch wafers at a time, instead of four, which was the existing standard. Picogiga planned to allocate specific reactors to the fabrication of HBT wafers in order to increase efficiency and yields. All of the new reactors, however, will be capable of producing both HEMT and HBT wafers. The company also purchased 8,000 m^2 of land adjacent to its existing facility to allow for future expansion (GaAsNet, July 11, 2000, Picogiga purchases more production equipment for 6 inch wafers, accessed July 17, 2000, at URL http://www.gaasnet.com/news/picogiga2_0700.html; GaAsNet, October 20, 2000, VG Semicon receives Picogiga orders for two V150 production MBE systems, accessed October 31, 2000, at URL http://www.gaasnet.com/ news/vg_20102000.html; GaAsNet, November 5, 2000, Picogiga purchases three Applied Epi production MBE systems, accessed November 8, 2000, at URL http://www.gaasnet.com/news/appliedepi_05112000.html). Picogiga exported most of its production, with about 70% sold in the United States.

Germany.—In March, GEO Gallium S.A., a subsidiary of GEO Specialty Chemicals Inc., announced that it would increase gallium extraction capacity at its Stade plant by more than 50% by the summer of 2000. The company also said that, since it acquired the gallium business from Rhodia Inc. in 1999, it had increased the capacity at its Salindres, France, gallium refinery by more than 30% (Compound Semiconductor, March 1, 2000, GEO Gallium S.A. to expand its gallium extraction plant in Stade, Germany, accessed November 2, 2000, at URL http://www.compoundsemiconductor.net/PressReleases/2000/PR030100005.htm). With the expansions, estimated annual capacity at the Stade plant was 30 t, and at Salindres, 26 t.

Japan.—Gallium supply in Japan in 2000 was estimated to be 158 t, a 39% increase from the 1999 level, and demand was estimated to be 140 t in 2000, a 21% increase from that in 1999. Of the supply, 14 t came from domestic production, 65.8 t from imports, and 93.7 t from recycled scrap. Japan's imports in 2000 mainly came from Kazakhstan (23%), the United States (23%), and France (21%). Smaller quantities were imported from China, Germany, Hungary, Russia, and Slovakia. Dowa Mining planned to increase its production of gallium to between 14 t and 15 t in 2001 from the 2000 level of 8 t. The company also was investing in technology to recycle low-grade scrap (Roskill's Letter from Japan, 2001).

Hitachi Cable Ltd. announced plans to expand its GaAs production facilities further. By June 2001, the company plans to increase its monthly capacities as follows: Liquid-encapsulated Czochralski (LEC) substrates to 45,000 4-inch wafers, about 2.3 times existing capacity; boat-grown and vertical-gradient-freeze (VGF) substrates to 95,000 wafers, about 1.5 times existing capacity; MOVPE wafers to 24,000 4-inch diameter wafers, about 3 times existing capacity; and liquid-phase-epitaxial wafers to 59,000 wafers, about 1.7 times existing capacity. Total investment for the increased capacity was estimated to be 12 billion yen (¥) ($98.4 million) in equipment and plant upgrades (Hitachi Cable Ltd., October 11, 2000, Investment in compound semi-conductor facilities is upwardly revised to 12 billion yen this fiscal year, accessed February 8, 2001, via URL http://www2.hitachi-cable.co.jp/apps/smcinfo.nsf/new).

Digitized by Google

In December, Matsushita Electronics Corp. announced that it would invest ¥22 billion ($198 million) to build a new 6-inch GaAs plant at its Uozu plant in Toyama Prefecture. Construction was scheduled to begin in January 2001, and the facility would be ready for operation in June 2002. This will be the company's second compound semiconductor production facility, and when finished, it will have a capacity of 6,000 6-inch wafers per month, more than double its existing output. The company said the new capacity is intended to keep up with growing demand from mobile appliance manufacturers. This would be the first 6-inch GaAs facility in Japan (Compound Semiconductor, 2000).

Fujitsu Quantum Devices was spending approximately $48 million to increase capacity at its 4-inch GaAs facility in Yamanashi Prefecture to 5,200 from 4,000 wafers per month. The company also planned to outsource some of its production so it would have a combined capacity equivalent to 8,000 4-inch wafers per month by the end of fiscal year 2002. In August, New Japan Radio Corp. announced that it planned to increase production of GaAs MMICs for use in mobile communications terminals. The company operated a 4-inch GaAs facility in Kawagoe (Compound Semiconductor, 2000).

Sumitomo Electric Industries planned to expand its manufacturing capabilities for GaAs. The company had invested more than ¥5 billion ($48 million) in new capital equipment for its existing compound semiconductor facility near Osaka, which resulted in increased GaAs substrate production in October. Sumitomo Electric Industries' 4-inch GaAs wafer capacity increased by 30%, 6-inch wafer capacity increased fivefold, and epitaxial wafer production tripled. Additional capacity expansion was already underway for 2001. The next phase of capital investment will increase not only GaAs substrates and epitaxial wafers but indium phosphide (InP) substrates as well (Compound Semiconductor, August 26, 2000, Sumitomo Electric expands capacity, accessed April 11, 2001, via URL http://www.compoundsemiconductor.net).

Toyoda Gosei Co. announced that it had begun mass producing GaN-base violet LEDs, becoming the world's first company to do so. Initially, the Toyota Motor Corp. affiliate will combine the LED with an optical catalyst for use in car air purifiers. The auto air purifier will decompose organic substances in the air into water and carbonic acid by exposing a titanium oxide optical catalyst to light from a violet LED. The device was installed in Toyota's remodeled Mark II passenger car released in October. The LED was expected to eventually be used in home electronics and lighting equipment, with projected annual sales of ¥1 billion ($8.2 million) in 2 to 3 years. Toyoda Gosei has already mass-produced green, blue, and blue-green LEDs. The 380-nanometer (nm) wavelength of the violet LED is shorter than that of other LEDs. Researchers at the firm added special materials in forming layers of GaN to produce the violet light. Toyoda Gosei and Nichia Corp. were suing each other over alleged LED patent infringements. In July, the Tokyo District Court ordered Toyoda Gosei to suspend production and sales of blue LEDs, and the firm took the case to a higher court (Compound Semiconductor, November 9, 2000, Toyoda Gosei mass produces violet LEDs, accessed April 17, 2001, via URL http://www.compoundsemiconductor.net).

Taiwan.—In December, WIN Semiconductors Corp. finished building the first 6-inch GaAs MMIC foundry in Taiwan. Initial production was expected to be 10,000 wafer starts per year. By 2004, when the foundry was expected to be running at capacity, production would be 100,000 wafer starts per year (WIN Semiconductors Corp., December 12, 2000, WIN Semiconductors' GaAs MMIC wafer fab is officially opened—Leading the industry into the era of 6" wafer foundry services, accessed April 10, 2001, at URL http://www.winfoundry.com/news-htm/News010108142614.htm).

Advanced Wireless Semiconductor Co. began construction of a 6-inch GaAs HBT processing line in June. The new line would complement the company's existing 4-inch line. Both lines would have the capability to process 600 wafers per week. Advanced Wireless also signed a multiyear agreement with U.S.-based Conexant in which Advanced Wireless would supply Conexant with an additional 30,000 wafer starts per year. Production began in the fourth quarter of 2000 (Tim Whitaker, Compound Semiconductor, 2000, Fab four address growing GaAs markets, accessed April 9, 2001, via URL http://www.compoundsemiconductor.net).

Two Taiwanese companies, United Epitaxy Co. (UEC) and Epistar Corp., placed orders for a total of 25 MOCVD systems. UEC ordered 20 systems, 10 each from AIXTRON and EMCORE. The AIXTRON systems will be used to produce aluminum indium gallium phosphide (AlInGaP) high-brightness LEDs and 4- and 6-inch HBT epiwafers and to manufacture nitride LEDs. EMCORE was scheduled to deliver 10 MOCVD systems to UEC by mid-2002. The new systems will be used to produce high-brightness LEDs and electronic materials. UEC already had six EMCORE systems, which were used for the production of AlInGaP LEDs. Epistar purchased five AIXTRON reactors as part of its new expansion scheme. The machines will be used for AlInGaP-based yellow, orange, and red high-brightness LEDs in addition to blue and green nitride wafer manufacturing (Compound Semiconductor, 2000, MOCVD spending spree in Taiwan, accessed April 11, 2001, via URL http://www.compoundsemiconductor.net).

United Kingdom.—A new company to manufacture compound semiconductors was started in 2000 using technology and equipment transferred from the University of Glasgow and the University of Strathclyde. Compound Semiconductor Technologies Ltd. opened a facility in Glasgow that could produce GaAs, InP, gallium arsenide phosphide, and gallium aluminum arsenide wafers. In addition, the company planned to produce GaN using technology from the University of Strathclyde. At yearend, the company was producing about 100 2- and 3-inch wafers per month, but the equipment has the capability to process 4-inch wafers (Compound Semiconductor Technologies Ltd., September 2000, Glasgow wafer fab in gallium nitride bid, accessed February 8, 2001, at URL http://www.compoundsemi.co.uk/news-waferfab.htm).

IQE plc, a manufacturer of epitaxial wafers, acquired Wafer Technology Ltd., a substrate supplier, in November. The acquisition would allow IQE to have a captive substrate supplier for its epitaxial production. Wafer Technology produced 2- to 4-inch GaAs and InP substrates, as well as specialty III-V substrates, using the LEC and VGF methods (GaAsNet, November 24, 2000, IQE acquires Wafer Technology Limited, accessed November 27, 2000, at URL http://www.gaasnet.com/news/iqe_24112000.html).

Filtronic Compound Semiconductors Ltd., a unit of Filtronic plc, opened its new GaAs fabrication plant in August. The company acquired the facility in Newton Aycliffe, County Durham, England, from Fujitsu Ltd. in 1999. The 28,800-m^2 facility was purchased for about $20 million with financial assistance from the United Kingdom Government. Filtronic invested about $56 million in a retrofit before starting

Digitized by Google

operations. Phase one of this plant was intended to provide a throughput of 30,000 6-inch wafers per year. This first stage utilizes about one-third of the available area, and Filtronic said that market demand would determine the future growth. Around 200 individual pieces of equipment had been purchased for the new plant, including 2 multiple-6-inch-wafer MBE systems. The company was also converting the former Litton Solid State Plant in Santa Clara, CA, to 6-inch operation, which would focus on process development and fast MMIC prototyping (Tim Whitaker, Compound Semiconductor, 2000, Fab four address growing GaAs markets, accessed April 9, 2001, via URL http://www.compoundsemiconductor.net).

Current Research and Technology

LumiLeds Lighting announced a breakthrough in its high-flux LEDs, with improvements in optical output power and efficiency. Aluminum indium gallium nitride (AlInGaN) technology is the standard technology for LEDs in the blue and green areas of the color spectrum. LumiLeds also has developed a unique power package that allows higher power LEDs to be housed and operated. Typical output of the new devices are blue LEDs, 100 milliwatts (mW) (5 to 8 lumens); green LEDs, 40 mW (10 to 20 lumens); and blue-green LEDs, 70 mW (15 to 25 lumens). By comparison, the industry standard 5-mm LED output was less than 10 mW in the blue spectrum. These devices also exhibited superior electrical and thermal characteristics. The new material was used in production LEDs beginning in November 2000 (LumiLeds Lighting, November 3, 2000, LumiLeds Lighting announces breakthrough in high-flux AlInGaN LEDs, accessed April 9, 2001, at URL http://www.lumileds.com/news/AlInGaN.html). LumiLeds Lighting is a joint venture between Agilent Technologies Inc. and Philips Lighting Co.

LumiLeds Lighting also announced a new product for channel-letter lighting that could replace neon as the primary lighting source in this application. The new "LED Rail" is a string of LEDs mounted on a patented rail system that allows for easy installation in standard channel letter housings. The LEDs are spaced such that they backlight the channel letter in a consistent manner. This was among the first solid-state lighting products on the market designed exclusively for channel letter lighting. The LED Rail contains no glass tubes. It is simply a string of wire with LED modules attached in fixed intervals. Glass can be a problem in signage because of breakage caused by harsh weather, transportation, and vandalism. The LED Rail operates at a lower voltage than neon, and it is easier to install than glass because there is no glass to bend. LumiLeds claimed that the LED Rail saves up to 80% of the energy used to light the same size neon-powered channel letters (Compound Semiconductor, March 31, 2000, LumiLeds Lighting introduces neon replacement solution for channel letter lighting using LEDs, accessed April 10, 2001, via URL http://www.compoundsemiconductor.net).

TriQuint received $3.1 million in funding from the U.S. Department of Commerce's National Institute of Standards and Technology to develop advanced, high-performance, low-cost GaAs-based HBT power amplifiers and incorporate them in compact multifunction chips for use in next-generation wireless communications and broadband cable systems. The 2.5-year project began in November, and the goal was to develop the HBT and build prototype cable television repeater amplifiers and circuits for advanced wireless base stations. TriQuint's partners in the project are ATMI and Linear Circuit Innovations Inc. (National Institute of Standards and Technology, October 2000, Advanced HBT power amplifier technology for broadband communications systems, accessed April 10, 2001, at URL http://jazz.nist.gov/atpcf/prjbriefs/prjbrief.cfm?ProjectNumber=00-00-4019).

Applied Optoelectronics Inc. (AOI) entered into a licensing agreement with Lucent Technologies Inc. that gave AOI the right to manufacture and distribute quantum-cascade lasers for applications in industries other than telecommunications. The agreement marked the first time Lucent had licensed this technology. AOI was pursuing sensor applications in markets such as combustion diagnostics, environmental sensing, medical diagnostics, industrial process control, and law enforcement, and the new lasers were expected to be commercially available by September 2000. The quantum-cascade laser was invented and demonstrated in 1994 at Bell Laboratories. It operates in the midinfrared portion of the spectrum, in which it previously had been difficult for scientists to create high-efficiency lasers. This spectral region is particularly important from an applications standpoint because many chemicals—including pollutants, industrial chemicals, explosives, and medically important substances—can only be sensitively detected using midinfrared lasers. Efforts to create high-performance, low-cost laser-based sensors for these materials had been hampered by the high price or limited spectral or power performance of existing lasers. The crystal structure of the quantum-cascade laser contains up to 1,000 alternating layers of different types of crystalline material, some thinner than one-billionth of an inch (Lucent Technologies Inc., July 12, 2000, Applied Optoelectronics, Inc. signs licensing agreement with Lucent Technologies, accessed August 17, 2000, at URL http://www.lucent.com/press/0700/000712.bla.html).

Researchers at the U.S. Naval Research Laboratory and at Sarnoff Laboratories announced the development of the first room-temperature III-V laser diode that emits light at a wavelength greater than 3 micrometers (μm). The diodes consist of 10 W-shaped quantum wells grown on a gallium antimonide substrate. The W structure consists of a central gallium indium antimonide hole sandwiched between two indium arsenide electron wells, which are in turn bracketed by two high aluminum gallium arsenide antimonide barriers. This structure allows excellent electron confinement, allowing a low threshold current, which enable continuous wave operation at relatively high temperatures (195 K). The research team's next goal was to have the device operate at temperatures above 230 K to avoid the need for cryogenic cooling. Potential applications for the devices include portable pollution monitors, medical diagnostics, and chemical weapons site detectors (Gaughan, 2000).

A research team at the Tokyo Institute of Technology created a hybrid iron and semiconductor material that changes magnetic properties when excited by light. The device consists of 20 alternating layers of ferrite and GaAs on a GaAs substrate. The researchers excited the device with light perpendicular to its surface and observed positive magnetoresistance. When the light was turned off, the magnetization returned to its original value, which indicates that the magnetization is reversible and not caused by a change in the structure of the device. If this is fully commercialized, it may lead to development of faster optical storage media and may also produce a new light-sensitive toner for photocopiers (Whipple, 2000).

In October, Isonics Corp., Golden, CO, and Epichem Inc.,

Digitized by Google

Allentown, PA, announced that they would establish a 2-year, jointly funded program to produced isotopically pure gallium for the semiconductor and optoelectronic business. The improved thermal conductivity provided by isotopically pure gallium can increase the performance and reliability some GaAs-base devices. Because the thermal conductivity of GaAs is about one-third that of silicon, improved thermal properties are likely to have substantial positive impact on the GaAs device performance (Isonics Corp., October 26, 2000, Isonics and Epichem start development of isotopically pure gallium, accessed November 2, 2000, at URL http://www.isonics.com/pr63.htm).

GaN continued to generate significant research interest at the academic level as well as on a commercial level. More than 100 companies and 200 universities worldwide were engaged in GaN material processing and device development. Europe with 37% and North America with 33% were the geographic areas where most of the groups were doing research and development (R.V. Steele, Compound Semiconductor, 2000, Update on GaN technology and markets, accessed April 9, 2001, via URL http://www.compoundsemiconductor.net). Much of the work centered on improving growth techniques and improving properties so that LEDs and laser diodes based on GaN technology could be commercialized.

AXT announced two new LED products, high-brightness cyan and green, which complimented the company's current offering of red, amber, yellow, and blue LEDs. The new 505-nm AlInGaN-based high-brightness cyan LED has a minimum power output of 1.2 mW at 20 milliamperes. High-brightness cyan LEDs were primarily used in traffic signals. Industry analysts estimated that the LED traffic signal market would reach approximately $100 million for 2000, and would grow at a rate of approximately 50% per year over the next few years. The new 525-nm AlInGaN-based high-brightness green LED has a minimum power output of 0.75 mW at 20 milliamperes. Because green is a primary color for light, by mixing red, green, and blue lights, many colors can be produced, including white light. With the high efficiency of this new product, many outdoor applications also would become feasible. High-brightness green LEDs were used in very large outdoor full-color displays, indoor displays, special-purpose illumination, cellular phone back lighting, traffic signals, as well as many consumer applications (Compound Semiconductor, April 28, 2000, American Xtal Technology announces new cyan and green LED products, accessed April 17, 2001, via URL http://www.compoundsemiconductor.net). The company received a multimillion dollar contract for the new LEDs in September.

Cree Inc., Durham, NC, reported it demonstrated the first MMIC made from GaN grown on a semi-insulating silicon carbide substrate. The initial device achieved 20 watts of pulsed radio frequency (RF) output power at 9 gigahertz (GHz), which exceeded the highest output power of GaAs MMICs available for this frequency range. The company also demonstrated a record-setting 10 GHz radio frequency power performance from a GaN HEMT. The GaN HEMT transistor was incorporated into a hybrid amplifier that achieved 40 watts of pulsed radio frequency output power at 10 GHz. This was more than 2.5 times higher than had been publicly reported for a single semiconductor device at this frequency. Cree's work on GaN hybrid and MMIC amplifiers was funded in part by the Air Force Research Laboratories and the Office of Naval Research, respectively. The GaN discrete devices and MMICs that were under development were being targeted for high frequency (5 to 35 GHz) commercial broadband communications, as well as military radar and communications applications (GaAsNet, August 19, 2000, Cree achieves record power performance at 10 GHz, accessed August 29, 2000, at URL http://www.gaasnet.com/news/cree_19082000.html).

Cree Lighting Co., a subsidiary of Cree, reported that it demonstrated a near-ultraviolet-violet indium gallium nitride LED with 28% quantum efficiency. This was the highest known external quantum efficiency publicly reported for an LED in the ultraviolet-to-blue portion of the wavelength spectrum. The LED emits at 400 nm and has a power output of 17 mW. LEDs in this portion of the light spectrum are important for making white solid-state light bulbs using phosphors to convert the wavelength of the light emitter to the visible spectrum, then mix colors to make a white bulb. High quantum efficiency is critical to making energy-efficient, solid-state light bulbs. The new emitter demonstrated an overall efficiency of 22% (Compound Semiconductor, July 28, 2000, Cree demonstrates 28% quantum efficient InGaN LED, accessed April 17, 2001, via URL http://www.compoundsemiconductor.net). Cree acquired Nitres Inc. in May 2000, renamed the company Cree Lighting, and began operating it as a wholly owned subsidiary. Nitres focuses on developing and commercializing nitride-based semiconductor materials and device technology; some research was funded though government and military contracts.

Cree and North Carolina State University filed a patent infringement lawsuit against Japan's Nichia Corp. and Nichia America Corp. in the U.S. District Court for the Eastern District of North Carolina. The lawsuit sought enforcement of a patent relating to GaN-based semiconductor devices manufactured using lateral epitaxial overgrowth (LEO) technology. The patent, U.S. patent No. 6,051,849, entitled "Gallium nitride semiconductor structures including a lateral gallium layer that extends from an underlying gallium nitride layer," was issued to North Carolina State University in April 2000 and was licensed to Cree under a June 1999 agreement from which Cree obtained rights to a number of LEO and related techniques. In its complaint, Cree alleges that Nichia was infringing the patent by importing, selling, and offering for sale in the United States certain GaN-based laser diodes covered by one or more claims of the patent. The lawsuit sought damages and an injunction against the infringement (Weiss, 2000).

Kyma Technologies Inc., a Research Triangle Park, NC, developer and supplier of nitride substrates, developed a 2-inch diameter, 50-μm thick epitaxial GaN layer, on a sapphire wafer, which was to be used as the core technology for a variety of applications within the optoelectronic, communications, and semiconductor industries. With existing technology, the typical epitaxial layer is 1 to 2 μm for sapphire-based GaN wafers. Kyma planned to ship samples to device developers by the end of 2000, with production quantities available in the first quarter of 2001 (Compound Semiconductor, November 2, 2000, 2-inch gallium nitride epitaxial substrate completed by Kyma Technologies, accessed April 17, 2001, via URL http://www.compoundsemiconductor.net).

ATMI developed and patented processes that allow the manufacture of high-purity GaN wafers 50 mm and larger in diameter; large area GaN wafers were not commercially available because of the difficulty of producing bulk GaN crystals. Based on their success with the patented technique, ATMI committed significant additional funding for continued

Digitized by Google

development and pilot manufacturing capacity. In addition, ATMI was awarded contracts totaling nearly $4 million from the Office of Naval Research and the Ballistic Missile Defense Organization for further development of GaN wafers for electronic and optoelectronic devices (Compound Semiconductor, October 17, 2000, A T M I announces optical materials initiative; gallium nitride wafer and epi expansion to support blue laser development, accessed April 17, 2001, via URL http://www.compoundsemiconductor.net).

Nitronex Corp., a Raleigh, NC, semiconductor startup, announced that it received $500,000 in venture capital from Centennial Venture Partners, a $10 million venture fund started by North Carolina State University to help launch start-up companies affiliated with the university. Nitronex, founded in 1998, was set to begin scaling its proprietary technology for growing GaN on silicon. The company's PENDEO™ process, developed with researchers at North Carolina State, allows it to combine GaN with silicon to take advantage of the properties of both materials (Compound Semiconductor, February 7, 2000, Nitronex lands additional venture capital, accessed April 17, 2001, via URL http://www.compoundsemiconductor.net).

In July, Spectrolab Inc., Sylmar, CA, a unit of Boeing Co., claimed to have set a new world record by manufacturing satellite solar cells able to convert 29% of the sun's rays into spacecraft power. This surpassed the company's previous record of 27%, announced in April, for a space solar cell, and came only 7 months after achieving a 32.3% efficiency in terrestrial solar cells. Spectrolab planned to start production of this triple-junction GaAs-base solar cell in the third quarter of 2000. The average maximum power efficiency was expected to be 27.4%, with an end-of-satellite-life efficiency of 24.1% after 15 years in geosynchronous orbit (Spectrolab Inc., July 12, 2000, Spectrolab sets new world record with space solar cell efficiency of 29 percent, accessed November 28, 2000, via URL http://www.spectrolab.com).

Spectrolab announced that it would supply its solar cells to Dornier Satellitensysteme GmbH (DSS) of Germany under a technical assistance agreement between the two companies for qualification testing in the DSS space solar array systems. This was the first European agreement for Spectrolab since it received U.S. Government approval to provide solar components to major European spacecraft manufacturers. DSS was expected to purchase several hundred thousand multijunction solar cells through 2002. Once they are qualified, Spectrolab's multijunction GaAs solar cells are expected to improve the DSS solar array power performance by 40% compared to earlier designs using silicon cells. These multijunction space solar cells have an average efficiency of 24.5% and were qualified by the major U.S. satellite manufacturers. Spectrolab had been working under a jointly funded development contract with the U.S. Air Force to deliver 35%-efficient space solar cells by 2002 (Spectrolab Inc., May 20, 2000, Spectrolab to supply solar cells to German satellite builder Dornier, accessed April 19, 2001, via URL http://www.spectrolab.com).

In June, EMCORE announced that the company's new triple-junction GaAs-base solar cells with 26% efficiency were in production and were being shipped to customers for space qualifications. During qualification testing, these cells demonstrated a power loss of only 8% under a typical 15-year geostationary orbit characteristic of communication satellites. These new solar cells were expected to significantly improve satellite communications economics by increasing payload capabilities (EMCORE Corp., June 27, 2000, EMCORE announces production of 26% efficiency triple-junction solar cells, accessed April 19, 2001, at URL http://www.emcore.com/html_documents/News_clips/2000/Triple_Junction.htm). The company also produced a dual-junction solar cell for satellite applications that has an efficiency ranking of 25.3%. The dual-junction InGaP/GaAs compound semiconductor solar cell product is grown on a germanium substrate (EMCORE Corp., February 2, 2000, EMCORE announces shipment of world's highest efficiency dual junction solar cells, accessed April 19, 2001, at URL http://www.emcore.com/html_documents/News_clips/2000/shipment_highest_efficency_solar_cell.htm).

Scientists at Sandia National Laboratories were investigating indium gallium arsenide nitride (InGaAsN) as a potential photovoltaic power source for space communications satellites. This material, which may be used as a solar cell, has a potential 40% efficiency rate when put into a multilayer cell, which is nearly twice the efficiency rate of a standard silicon solar cell. An InGaAsN solar cell that could provide power to a satellite would ultimately have four layers. The top layer would consist of indium gallium phosphide, the second of GaAs, the third of 2% nitrogen with indium in GaAs, and the fourth of germanium. Each layer absorbs light at different wavelengths of the solar spectrum. The first layer absorbs yellow and green light, the second absorbs between green and deep red, the third absorbs between deep red and infrared, and the fourth absorbs infrared and far infrared. The absorbed light creates electron hole pairs. Electrons are drawn to one terminal and the holes to the other, thus producing electrical current (U.S. Department of Energy, Sandia National Laboratories, March 8, 2000, New semiconductor alloy's 'crazy physics' makes it a possible photovoltaic power source for satellites, accessed June 16, 2000, at URL http://www.sandia.gov/media/NewsRel/NR2000/InGaAsN.htm).

Also at Sandia, researchers constructed a two-dimensional GaAs artificial crystal that conducts light. The crystal's appearance resembles that of cheesecloth; this structure could be considered essentially a wire for light, because the specific size and periodic placement of the holes create a structure that blocks most light waves while transmitting those in a selected band of wavelengths. Because of the very small light loss, the technique offered the potential of ultimately replacing electronic chips with faster, cooler photonic chips. The technique could be used to combine light with electrons in a single chip. It also could be used to relay and change the direction of optical signals coming through telecommunications lines. The GaAs structure potentially may significantly reduce the energy needed to start and operate a laser. Although researchers say that the crystal structure was easy to fabricate, it was difficult to build and test without the structure cracking (U.S. Department of Energy, Sandia National Laboratories, October 27, 2000, Cheesecloth-like device bends light with little loss, accessed April 24, 2001, at URL http://www.sandia.gov/media/NewsRel/NR2000/cheese.htm).

Working with colleagues at Brown University, research personnel at Sandia demonstrated a prototype of the first VCSEL that emits ultraviolet light. While project work had been ongoing for 3 years, a key advance took place when indium was added to the VCSEL materials mix in August 1999. VCSELs are made of nanoscopically thin layers of semiconductor materials that emit photons when electricity is passed through them. While GaN and aluminum nitride both emit in the ultraviolet range, the efficiency with which those

Digitized by Google

materials make use of input power is not high, only about 1%. Adding indium brought the VCSEL efficiency to a starting point of 20%, although it pushed the wavelength emitted longer into the near-ultraviolet range, about 380 nm. The successful synthesis of highly reflective bottom mirrors from aluminum gallium nitride was another important factor in making the prototype. Among their benefits, ultraviolet VCSELs coated with phosphors have the capability to generate the white light that could be used in indoor lighting. Easily portable ultraviolet laser light also causes weapons-grade fissionable materials and *E. coli* bacteria to fluoresce in the visible spectrum, aiding in the detection of attempted materials thefts and preventing the spread of bacterial epidemics (U.S. Department of Energy, Sandia National Laboratories, October 17, 2000, Sandia VCSEL generates ultraviolet light, accessed April 24, 2001, at URL http://www.sandia.gov/media/NewsRel/NR2000/UVVCSEL.htm).

Outlook

According to information compiled by CIBC World Markets, a unit of the Canadian Imperial Bank of Commerce, the GaAs industry is expected to decline in 2001, the first significant downturn in this industry. The company predicts that unless the cellular phone business shows a significant turnaround, GaAs sales could decline by as much as 15% in 2001. CIBC projected that the total number of mobile phone handsets sales in 2001 would be about 475 million units, an increase from the 410 million units sold in 2000. But there is significant inventory in this industry, which would be sufficient to supply the increase in demand, so the net gain would be essentially zero (Compound Semiconductor, 2001). According to CIBC, the leading world suppliers, based on a percentage of the value in 1999, are Fujitsu (11.1%), Mitsubishi Electric Corp. (10.1%), RF Micro Devices (9.6%), Motorola (7.4%), and Conexant (6.7%).

With a growth rate exceeding 58% per year for the past 5 years, Strategies Unlimited projected that the worldwide market for high-brightness LEDs reached $1.2 billion in 2000 and accounted for 42% of the total LED market. The company projected continued robust growth for the next 5 years, with the market expected to exceed $3.4 billion in 2005 (Compound SemiOnline, April 6, 2001, High brightness LED market forecast to reach $3.4 billion by 2005, accessed May 22, 2001, at URL http://compoundsemi.com/documents/view/generic.php3?id=389#top). The company expects that such markets as backlighting for mobile phones may experience a slowdown, but demand for very-high-brightness products for outside video displays, signage, and traffic signals will remain strong.

Until recently, the only significant market for GaN devices has been for high-brightness blue, green, and white LEDs. Since the announcement of high-brightness GaN-based blue LEDs in late 1993, the market grew from virtually nothing to $420 million by 1999. Since 1995, the growth rate had been estimated to be 79% per year. GaN-based blue, green, and white LEDs are used in a variety of applications, including full-color outdoor signs, automotive interior lighting, traffic signals, backlights for cell phone displays, niche illumination applications, and general purpose indicator and display applications. GaN-based blue-violet laser diodes operating at 405 nm, developed by Nichia, were introduced to the market on a sample basis in early 1999. These devices are used in a variety of applications, including sensing, spectroscopy, laboratory research and next-generation optical storage system development. No commercial blue-laser-based optical storage systems had been introduced. The GaN device market, however, was projected to experience strong growth over the next decade. Blue laser diodes will begin to be used in high-density DVD drives in 2002 and will capture a large share of the optical storage market in subsequent years. The total GaN device market was projected to grow to more than $4.8 billion by 2009 representing a compound annual growth rate of 28% from 1999 (R.V. Steele, Compound Semiconductor, 2000, Update on GaN technology and markets, accessed April 9, 2001, via URL http://www.compoundsemiconductor.net).

Forecasts of large growth in demand for gallium-based devices are based on the assumption of no significant changes in the overall world economy. If there is a significant decline in the world economy, these growth scenarios are too optimistic. Any growth in the use of gallium-based devices, however, will require additional gallium production capacity to be constructed. At current rates of world consumption, there is not enough virgin gallium supply available, as is evidenced by the situation at yearend 2000. Some of the supply problems should be alleviated when GEO Gallium's 100-t/yr gallium extraction plant comes on-stream in Australia in 2002.

GARNET, INDUSTRIAL

By Donald W. Olson

Domestic survey data and tables were prepared by Christine K. Pisut, statistical assistant.

The angular fractures and high hardness of garnet and its ability to be recycled make it desirable for a variety of abrasive purposes. The complex mineralogy of garnet determines its utility for a variety of uses ranging from a filtration medium to a waterjet abrasive.

Garnet is the general name for a group of complex silicate minerals with similar crystalline structures and diverse chemical compositions. The general chemical formula is $A_3B_2(SiO_4)_3$, where "A" can be calcium, magnesium, ferrous iron, or manganese, and "B" can be aluminum, chromium, ferric iron, or rarely, titanium. Garnet occurs worldwide in many rock types, principally gneisses and schists; other sources include contact metamorphic rocks, crystalline limestones, pegmatites, and serpentinites. Alluvial garnet is associated with heavy mineral sand and gravel deposits in many parts of the world. Occurrences of garnet are large and numerous; however, relatively few commercially viable garnet deposits have been discovered.

Mine output of industrial garnet in the United States decreased slightly in 2000 compared with that of 1999, while the value of U.S. industrial garnet production increased by about 14% over that of 1999. The one mining operation in the United States that had closed down in 1999 was purchased during 2000 and began producing from stocks.

Production

The U.S. industrial garnet industry is dominated by a few major producers. The industrial garnet market is influenced by the size and grade of reserves, the type and quality of garnet mined, the proximity of deposits to infrastructure and consumers, and the milling costs. Pricing within the U.S. garnet industry is very competitive, and suppliers must provide a high level of customer service. Most industrial-grade garnet mined in the United States is almandine (iron-aluminum silicate) and pyrope (magnesium-aluminum silicate), although andradite (calcium-iron silicate) is also a domestic source for industrial uses.

The United States produced approximately 20% of the industrial garnet mined worldwide in 2000. According to a survey conducted by the U.S. Geological Survey (USGS), five U.S. companies in Idaho, Montana, and New York accounted for all domestic output. Production decreased slightly to 60,200 metric tons (t), whereas the value of annual production grew by 14% to about $7.1 million in 2000 (table 1). The producers were Barton Mines Co. LLC in Warren County, NY; Emerald Creek Garnet Co. in Benewah County, ID; Montana-Oregon Investment Group LLC in Madison County, MT; NYCO Minerals, Inc. in Essex County, NY; Patterson Materials Corp.

Industrial Garnet in the 20th Century

Garnet is mined as a gemstone and an industrial material, but it is valued primarily for its many industrial applications. The United States developed substantial garnet abrasive technology and applications earlier than other countries mainly because of the large deposits of high-quality abrasive garnet in New York. The deposits were first commercially developed in 1878. In 1900, annual production of industrial garnet in the United States was about 2,890 metric tons valued at about $123,000. Production was primarily in Maine, New York, North Carolina, Pennsylvania, and Virginia. There are no data to indicate that the United States had any foreign trade in industrial garnet in 1900. The price at the mine varied from $25 to $60 per ton. The main use for industrial garnet was in the sandpaper industry. At the end of World War II in 1945, U.S. industrial garnet production and consumption began a steady rise that roughly paralleled the rise in new home starts. The most significant jump in U.S. garnet production and consumption began in 1987, when health risks were first associated with the inhalation of airborne crystalline silica dust, and garnet began to replace crystalline silica as a sand blasting medium.

In 2000, domestic crude garnet production was estimated to be 60,200 tons, with an estimated value of more than $7 million; the value of refined garnet material was estimated to be $14 million. Garnet for industrial use was mined in 2000 by five firms: three in New York, one in Idaho, and one in Montana. In 2000, U.S. imports and exports of industrial garnet were about 23,000 tons and 10,000 tons, respectively. Imports were mostly from Australia, India, and China. Domestic consumption of garnet was estimated to be about 25,000 tons. Values for crude concentrates ranged from about $53 to $254 per ton, and values for refined garnet ranged from $61 to $441 per ton. By the end of the 20th century, major end uses for industrial garnet in the United States were abrasive sand blasting media, filtration media, precision abrasive powders, waterjet abrasives, and other miscellaneous abrasive uses, ranging from nonskid surfaces to finishing of plastic and wood products. In 2000, industrial garnet was still gradually displacing crystalline silica sand in the blast cleaning market, due to the health risks associated with the use of crystalline silica and due to garnet's ability to be recycled for reuse several times.

Digitized by Google

in Dutchess County, NY; and Sweetwater Garnet Inc. in Madison County, MT. All but one of the producers reported their output and sales to the USGS, and production and values for the nonreporting company were estimated. In addition to the producers cited above, International Garnet Abrasive Inc. in Clinton County, NY, processed and sold all of the garnet mined by NYCO Minerals in 2000.

Sweetwater Garnet, which had shut down in 1999, was sold in July 2000 to Stansbury Holdings Corporation. In the fall of 2000, Stansbury resumed operations at Sweetwater after upgrading the mill and was producing from stocks.

Consumption

The United States was the world's largest consumer of industrial garnet, accounting for 20% to 25% of global consumption (Harris, 2000). In 2000, the U.S. apparent consumption of industrial garnet was estimated to be 25,400 t, which was a 45% decrease from the 1999 apparent consumption. This apparent consumption decrease was due to a 75% increase in U.S. producer stocks. Most of these stocks were concentrated in two of the U.S. industry's five producers.

Major end uses in the United States and their estimated market share were abrasive blasting media, 45%; water filtration, 15%; abrasive powders, 10%; waterjet cutting, 10%; and other miscellaneous abrasive uses, 20%. Domestic consumption approximated world demand patterns, except that filtration uses abroad accounted for a greater market share. U.S. industries that consumed industrial garnet included aircraft manufacturers, ceramics and glass producers, electronic component manufacturers, motor vehicle manufacturers, the petroleum industry, shipbuilders, water filtration plants, and wood-furniture-finishing operations.

The majority of industrial garnet is used as a loose-grain abrasive because of its hardness, which ranges from 6 to 7.5 on the Mohs scale. Lower-quality industrial garnet is used as a filtration medium in water-purification systems because of its relative inertness and chemical degradation resistance. High-quality, high-value garnet grain has been used principally for such applications as optical lens grinding and plate-glass grinding for more than a century; industrial diamond and fused aluminum oxide are competitors in this application. In recent years, industrial garnet powders have been used for high-quality, scratch-free lapping of semiconductor materials and other metals. Other applications include the manufacture of coated abrasives; hydrocutting; and the finishing of wood, leather, hard rubber, felt, and plastics. Garnet has been slowly replacing silica sand in the blast cleaning market. This market displacement is happening because of the health risks associated with the inhalation of airborne crystalline silica dust having curtailed its use, but silica sand and slag are still the most widely used media in blasting (Harris, 2000).

The U.S. petroleum industry is one of the largest garnet-consuming industries, using garnet for cleaning drill pipes and well casings. Huge crude oil price increases during 2000 allowed for the performance of previously deferred equipment maintenance activities and increased the petroleum industry's use of industrial garnet (Frank Alsobrook, President, Alsobrook and Company, Inc., oral commun., November 8, 2000).

The shipbuilding and aluminum aircraft industries use garnet for blast cleaning and for finishing metal surfaces. Similar uses include the cleaning and conditioning of aluminum and other soft metals, as well as metal cleaning by structural steel fabrication shops. Mixed-media water filtration, using a mixture of sand, anthracite, and garnet, has displaced older filtration methods because it is more reliable and provides better water quality; ilmenite, magnetite, and plastics compete as filtration media. Garnet entrained in high-pressure streams of water is also used to cut many different materials. The garnet powders generally are used for glass/ceramic polishes, antislip paints, and antiskid surfaces.

In the coated-abrasive market, garnet has an intermediate place between low-cost quartz sand or staurolite and such more costly manufactured abrasives as silicon carbide and fused alumina; garnet is more efficient than quartz sand in most coated-abrasive applications. Because of its friable nature and lower hardness, garnet cannot compete with manufactured abrasives in metalworking applications that require substantial metal removal.

Prices

The wide price range of industrial garnet was based on the type, source, quantity purchased, quality, and application. In 2000, average values for crude concentrates ranged from about $53 to $254 per ton, and average values for refined garnet sold during the year ranged from $61 to $265 per ton. However, spot prices reached as high as $441 per ton. Quantities sold by U.S. producers increased by approximately 17%, and the value of sales increased by about 21% during 2000.

Foreign Trade

The U.S. Government no longer compiles trade data that can be used to identify garnet exports and imports specifically. Based on reports from some producers and other industry sources, however, exports and imports of industrial garnet were estimated to be about 10,000 t and 23,000 t, respectively, in 2000. Some of the imports were not consumed during the year. Most U.S. garnet exports went to Asian and European markets.

About 40% to 45% of the U.S. garnet imports were from Australia, 35% to 40% from India, and 15% from China (Frank Alsobrook, President, Alsobrook and Company, Inc., oral commun., November 8, 2000). Australia historically has accounted for most of the industrial garnet imported by the United States. Imports of garnet from India are increasing, and both China and India have the potential to gain a significant share of the U.S. market (Frank Alsobrook, President, Alsobrook and Company, Inc., oral commun., November 8, 2000).

World Review

Total world industrial garnet production was estimated to be 335,000 t (Roskill Information Services Ltd., 2000). Australia, China, India, and the United States were the most significant producers in 2000. The United States produced approximately 20% of the industrial garnet mined worldwide. Australia and India exceeded U.S. production. Russia and Turkey have been

Digitized by Google

mining garnet in recent years, primarily for domestic markets. Additional garnet resources with small mining operations are located in Canada, Chile, the Czech Republic, Pakistan, South Africa, Spain, Thailand, and Ukraine. Output in most of these countries is for domestic use (Frank Alsobrook, President, Alsobrook and Company, Inc., oral commun., November 8, 2000).

Australian exports of garnet are expected to continue to increase. China and India also have increased garnet output and are likely to become more significant garnet sources for other countries.

Outlook

Industrial garnet sold by U.S. producers increased by about 17% during 2000, and some forecasts indicate that domestic markets for industrial garnet may continue to grow in the next several years. Worldwide industrial garnet demand is expected to grow over the next 5 years at a rate of 3% to 5% per year. Markets for waterjet cutting and blasting media are expected to exhibit the highest growth (Roskill Information Services Ltd., 2000). With recent worldwide increases in petroleum prices, there has been an increase in petroleum exploration and in the use of garnet blasting media for cleaning drill pipe by the oil and gas industry. Increased defense spending in the United States could lead to increased garnet demand, since the aircraft manufacturing and shipbuilding industries use significant amounts for blast cleaning and finishing of metal surfaces. Substitution for silica sand by garnet in abrasive blasting markets will also continue but at a pace slower than expected by the most optimistic forecasts because silica sand has a price advantage and is more accessible to consumers. Growing world demand encourages new companies to enter the garnet industry, but the current major producers will continue to be the dominant suppliers in the first decade of the 21st century.

Increased producer stocks are being reported in the United States, and significant stocks of industrial garnet are held in Australia and India. These excess production stocks coupled with possible future expansions will not only meet anticipated market needs, but may also result in widespread garnet price decreases until supply and demand come into balance.

GEMSTONES

By Donald W. Olson

Domestic survey data and tables were prepared by Christine K. Pisut, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Humans have been intrigued by gems since prehistoric times. They have been valued as treasured objects throughout history by all societies in all parts of the world. The first stones known to have been used for making jewelry include amber, amethyst, coral, diamond, emerald, garnet, jade, jasper, lapis lazuli, pearl, rock crystal, ruby, serpentine, and turquoise. These stones served as status symbols for the wealthy. Today, gems are not worn to demonstrate wealth as much as they are for pleasure or in appreciation of their beauty (Schumann, 1998, p. 8). In this report, the terms "gem" and "gemstone" mean any mineral or organic material (such as amber, pearl, and petrified wood) used for personal adornment, display, or object of art because it possesses beauty, rarity, and durability. Of the 2,700 mineral species, only about 100 possess all these attributes. Silicates compose the largest group of gemstones; oxides and quartz compose the second largest (table 1). A further subcategory of gemstones is "colored gemstone," which in this report designates all nondiamond gemstones, including amber, coral, and shell. In addition, synthetic gemstones, cultured pearls, and gemstone simulants are discussed but are treated separately from natural gemstones (table 2). Current information on industrial-grade diamond can be found in the U.S. Geological Survey (USGS) minerals yearbook chapter on industrial diamond.

Production

Commercial mining of gemstones has never been extensive in the United States. More than 60 varieties of gemstones have been produced commercially from domestic mines, but most of the deposits have been relatively small compared with other mining operations. In many instances, contemporary gemstone mining in the United States is conducted by hobbyists, collectors, and gem clubs rather than business organizations.

The commercial gemstone industry in the United States consists of several distinct sectors: (1) individuals and companies that mine gemstones or harvest shell and pearl, (2) firms that manufacture synthetic gemstones, and (3) individuals and companies that cut natural and synthetic gemstones. The domestic gemstone industry is focused on the production of colored gemstones and on the cutting of large diamonds. Industry employment is estimated to range from 1,000 to 1,500 workers (U.S. International Trade Commission, 1997, p. 1).

Most natural gemstone producers in the United States are small businesses that are widely dispersed and operate independently. The small producers probably have an average of less than three employees, including those who only work part time. The number of gemstone mines operating from year to year fluctuates, because the inherent uncertainty associated with the discovery and marketing of gem-quality minerals makes it difficult to obtain financing for developing and sustaining economically viable deposits (U.S. International Trade Commission, 1997, p. 23).

The total value of natural gemstones produced in the United States during 2000 was estimated to be at least $17.2 million (table 3). The production value was 6.9% greater than the preceding year. The production growth was mostly because the 2000 shell harvest was 42% larger than in 1999 and foreign markets for U.S. shell material grew as the demand from Southeast Asia cultured pearl producers increased (Jewellery News Asia, 2000b).

The estimate of 2000 U.S. gemstone production was based on

Gemstones in the 20th Century

In 1900, U.S. production of gemstones was valued at about $233,000. The top five gemstone types, in descending order of production value, were turquoise, sapphire, rhodolite (garnet), aquamarine, and quartz crystal; these accounted for about 85% of total domestic production. Turquoise was produced primarily in Nevada and New Mexico. Sapphire production was in Montana, rhodolite and beryl production occurred in North Carolina, and quartz crystal production was in California and Montana. In 1900, the United States also imported diamond and other gemstones valued at about $13.6 million. Nearly $4 million worth of these imports were rough South African diamonds that were all cut in the United States. Opals from Australia that were cut in the United States were also a significant portion of these imports.

In 2000, domestic gemstone production was estimated to be $74.3 million, of which an estimated $57.1 million was synthetic gemstone and $17.2 million was natural gemstone. The top seven natural gemstone types, in descending order of production value, were shell, beryl, agate, turquoise, quartz, coral, and gem feldspars; these accounted for about 47% of the total natural gemstone production. Output of natural gemstones was primarily from Tennessee, Arizona, California, Nevada, and Utah, in decreasing order. Reported output of synthetic gemstones was from five firms in North Carolina, New York, Florida, California, and Arizona, in decreasing order of production. There was notable production of freshwater pearl in Tennessee, turquoise in Arizona, and beryl in North Carolina and Utah. In 2000, the United States also imported diamond and other gemstones valued at about $12.9 billion. Of these imports, 79% was from Israel, India, and Belgium, in descending order of gemstone import value. Diamond imports accounted for 93% of the total value of gemstone imports, and slightly more than 10.4% by weight of those diamonds was cut in the United States.

Digitized by Google

a survey of more than 200 domestic gemstone producers conducted by the USGS. The survey provided a foundation for projecting the scope and level of domestic gemstone production during the year. However, the USGS survey did not represent all gemstone activity in the United States, which includes thousands of professional and amateur collectors. Consequently, the USGS supplemented its survey with estimates of domestic gemstone production from related published data, contacts with gemstone dealers and collectors, and information garnered at gem and mineral shows.

Natural gemstone materials indigenous to the United States are collected, produced, and/or marketed in every State. During 2000, all 50 States produced at least $1,000 worth of gemstone materials. Five States accounted for about than 75% of the total value, as reported by survey respondents. These States, in order of declining value of production, were Tennessee, Arizona, California, Nevada, and Utah. Some States were known for the production of a single gemstone material, Tennessee for freshwater pearls and Arkansas for quartz, for example. Other States produced a variety of gemstones, like Arizona, whose gemstone deposits included agate, amethyst, azurite, chrysocolla, fire agate, garnet, jade, malachite, obsidian, onyx, peridot, petrified wood, opal, smithsonite, and turquoise. A wide variety of gemstones also were found in California, Idaho, Montana, and North Carolina.

There were only two operations on significant known diamond-bearing areas in the United States during 2000. The first is the Kelsey Lake Diamond Mine, which straddles the Colorado-Wyoming State line. Kelsey Lake is now the only commercial producing diamond mine in the United States. It is operated by Great Western Diamond Co., a wholly-owned subsidiary of McKenzie Bay International Ltd., who purchased the property from Redaurum Ltd. in April 2000 (McKenzie Bay International Ltd., May 1, 2000, Kelsey Lake Diamond Mine released from bankruptcy proceedings Yes International to perform investor relations, accessed November 20, 2000, at URL http://www.mckenziebay.com/news/archive/000501.htm). Diamonds are present in three of the nine known kimberlite pipes on the Kelsey Lake property. The remaining six kimberlites have yet to be fully explored and tested for their diamond potential. Of diamonds recovered, 50% to 65% were clear gem quality, and almost a third were 1 carat or larger in size. The identified resources are at least 17 million tons (Mt) grading at an average of 4 carats per hundred tons (J. Taylor, April 11, 2000, McKenzie Bay International Ltd., accessed July 16, 2001, at URL http://www.mckensiebay.com/reports/jt000411.htm). Kelsey Lake was reopened and began production again in September 2000, after installing new equipment in the main processing and recovery plant. Maximum diamond recovery rates are expected in 2001 (McKenzie Bay International Ltd., September 6, 2000, Diamond production begins at Kelsey Lake Diamond Mine, accessed November 20, 2000, at URL http://www.mckenziebay.com/news/archive/000906.htm). The second operation was in Crater of Diamonds State Park near Murfreesboro in Pike County, AR, where a dig-for-fee operation for tourists and rockhounds is maintained by the State. Crater of Diamonds is the only diamond mine in the world that is open to the public. The diamonds occur in a lamproite breccia tuff associated with an extinct volcanic pipe and in the soil developed from the lamproite breccia tuff. Since the diamond-bearing pipe and the adjoining area became a State park in 1972, over 21,000 diamonds have been recovered. Recent exploration demonstrated that there are some 78.5 Mt of diamond-bearing rock in this diamond deposit (Howard, 1999, p. 62). An Arkansas law, enacted early in 1999, prohibits commercial diamond mining in the park (Diamond Registry Bulletin, 1999).

In addition to natural gemstones, synthetic gemstones and gemstone simulants are produced in the United States. Synthetic gemstones have the same optical, physical, and chemical properties as the natural materials that they appear to be. Simulants have an appearance similar to that of a natural gemstone material, but they have different optical, physical, and chemical properties. Synthetic gemstones produced in the United States include alexandrite, diamond, emerald, moissanite, ruby, sapphire, turquoise, and zirconia. Simulants of coral, lapis lazuli, malachite, and turquoise also are manufactured. In addition, certain colors of synthetic sapphire and spinel, used to represent other gemstones, are classified as simulants.

Synthetic gemstone production in the United States exceeded $57 million during 2000; simulant gemstone output was even greater and was estimated to be more than $100 million. Five firms in five States, representing virtually all the U.S. synthetic gemstone industry, reported production to the USGS. The States with reported synthetic gemstone production were Arizona, California, Florida, New York, and North Carolina. At least one U.S. company has developed technology to produce consistent quality and quantities of synthetic diamond and has reported production during 2000. The synthetic diamond stones weight ranged from 1.5 to 2 carats.

In 2000, a North Carolina firm entered its third year of marketing moissanite, a gem-quality synthetic silicon carbide that it produces. Moissanite is also an excellent diamond simulant, but it is being marketed for its own gem qualities.

Consumption

Although the United States accounts for less than 1% of total global gemstone production, it is the world's leading gemstone market. On the basis of indicators, such as trade data and income growth rates, U.S. gemstone markets—bolstered by strong demand among consumers with more personal wealth and more discretionary income—apparently accounted for at least 35% of world gemstone demand in 2000. The U.S. market for unset gem-quality diamonds during the year was estimated to have exceeded $9 billion, the largest in the world. Domestic markets for natural, unset nondiamond gemstones totaled about $770 million.

According to a poll conducted by a U.S. jewelry retailers association in the mid-1990s, about two-thirds of domestic consumers who were surveyed preferred diamond as their favorite gemstone (ICA Gazette, 1996). In 2000, the top-selling colored gemstones, in descending order, were blue sapphire, ruby, emerald, amethyst, tanzanite, tourmaline, garnet, fancy sapphire, pearl, and blue topaz (Prost, 2001). In addition to jewelry, gemstones are used for collections, exhibits, and decorative art objects.

Prices

Gemstone prices are governed by many factors and qualitative characteristics, including beauty, clarity, defects,

Digitized by Google

demand, and rarity. Diamond pricing, in particular, is complex; values can vary significantly depending on time, place, and the subjective evaluations of buyers and sellers. There are more than 14,000 categories used to assess rough diamond and more than 100,000 different combinations of carat, clarity, color, and cut values used to assess polished diamond (Pearson, 1998).

Colored gemstone prices are generally influenced by market supply and demand considerations, and diamond prices are supported by producer controls on the quantity and quality of supply. Values and prices of gemstones produced and/or sold in the United States are listed in tables 3 through 5. In addition, customs values for diamonds and other gemstones imported, exported, or reexported are listed in tables 6 through 10.

De Beers Consolidated Mines Ltd. in South Africa is a significant force affecting gem diamond prices worldwide because it mines about one-half of the diamonds produced each year and sorts and values about two-thirds (by value) of the world's annual supply of rough diamonds through its Diamond Trading Co. (DTC), which has marketing agreements with other producers. Estimates based on the reported output of major diamond mines in 2000 indicate that the average value of all diamond produced during the year was about $71 per carat; by country, the average value per carat ranged from about $14 in Australia to more than $276 in Namibia (Luc Rombouts, Terraconsult bvba, May 2, 2001, Diamond annual review—2000, accessed June 19, 2001, at URL http://www.terraconsult.be/overview.htm).

Foreign Trade

During 2000, total U.S. gemstone trade with all countries and territories exceeded $17.4 billion; diamonds accounted for about 92% of the total. In 2000, U.S. exports and reexports of diamond were shipped to 72 countries and territories, and imports of all gemstones were received from 112 countries and territories (tables 6-10).

During 2000, U.S. trade in cut diamonds reached unprecedented levels; the country continued to be the world's leading diamond importer and set export records as well. Record high imports were attributed to a relatively strong U.S. economy that boosted domestic demand for diamond jewelry among consumers with more personal wealth and discretionary income.

The United States is a significant international diamond transit center, as well as the world's largest gem diamond market. The large volume of reexports (table 6) shipped to other centers reveals the significance that the United States has in the world's diamond supply network.

Synthetic gemstone trade continued to increase for the United States in 2000. Imports of synthetic gems increased slightly during the year. Synthetic gemstone imports from Austria, China, Germany, Switzerland, and Thailand made up about 80% of the total domestic imports of synthetic gemstones during the year. Prices of certain synthetic gemstone imports, such as amethyst, were very competitive. The marketing of synthetic imports and enhanced gemstones as natural gemstones and the mixing of synthetic materials with natural stones in imported parcels continued to be problems for some domestic producers in 2000. Another problem during the year was that some simulants were being marketed as synthetic gemstones.

World Review

The gemstone industry worldwide has two distinct sectors: (1) diamond mining and marketing, and (2) the production and sale of colored gemstones. Most diamond supplies are controlled by a few major mining companies; prices are supported by managing the quantity and quality of the gemstones relative to demand, a function performed by De Beers through DTC. Unlike diamonds, colored gemstones are primarily produced at relatively small, low-cost operations with few dominant producers; prices are influenced by consumer demand in addition to supply availability.

In 2000, world diamond production totaled at least 118 million carats with an estimated value of more than $7.86 billion (table 11). Most production was concentrated in a few regions—Africa [Angola, Botswana, Congo (Kinshasa), Namibia, and South Africa], Asia (northeastern Siberia and Yakutia in Russia), Australia, North America (Northwest Territories in Canada), and South America (Brazil and Venezuela). In 2000, Botswana was the world's leading diamond producer in terms of output value and quantity (Luc Rombouts, Terraconsult bvba, May 2, 2001, Diamond annual review—2000, accessed June 19, 2001, at URL http://www.terraconsult.be/overview.htm).

Global diamond sales hit a record high of $25.8 billion, nearly 9% higher than 1999, according to figures released by the Diamond High Council (CNN.com, January 30, 2001, Diamond sales enjoy record year, accessed February 2, 2001, at URL http://www.cnn.com/2001/WORLD/europe/01/30/belgium.diamonds/index.html). Record sales of rough diamond by DTC in 2000 reached $5.67 billion, 8.2% higher than the 1999 total of $5.24 billion. The sales record was primarily the result of very strong sales in the first half of the year. Sales in the second half of the year actually dropped by 23% compared with the second half of 1999 (The Diamond Registry, January 2001, U.S. market drives De Beers to record sales increase in 2000, accessed April 25, 2001, at URL http://www.diamondregistry.com/News/sales_record.htm). Retail diamond jewelry sales in the United States grew by 6% in 2000, the ninth consecutive year sales have risen (Diamond Registry Bulletin, 2001a).

Additional events significant to diamond mining and marketing worldwide in 2000 include the following:

- The Ekati Mine, Canada's first commercial diamond mine, completed its second full year of production. The Ekati Mine, located in the Northwest Territories, was a joint venture between BHP Diamonds Inc. (BHP) and Dia Met Minerals Ltd., but in June 2001, BHP purchased Dia Met Minerals Ltd. (BHP Diamonds Inc., 2001). Ekati has estimated reserves of 60.3 Mt of ore in kimberlite pipes, containing 54.3 million carats of diamonds, and the mine life is projected to be 25 years. In 2000, Ekati produced 2.63 million carats valued at $454 million, which reflected a record sales price of $172.52 per carat. Ekati diamonds are sold by the BHP sales office in Antwerp (65%) and by DTC (35%) (Luc Rombouts, Terraconsult bvba, May 2, 2001, Diamond annual review—2000, accessed June 19, 2001, at URL http://www.terraconsult.be/overview.htm).
- The Diavik diamonds project is located in the Northwest Territories. Diavik has estimated reserves of 25.6 Mt of ore in kimberlite pipes, containing 102 million carats of diamonds, and the mine life is projected to be 20 years.

Digitized by Google

Diavik received the required permits and regulatory approval in 2000 and began site infrastructure development and project construction. Diavik is an unincorporated joint venture between Diavik Diamond Mines Inc. (60%) and Aber Diamond Mines Ltd. (40%), and it is expected to commence diamond production in the first half of 2003. The mine is expected to produce about 102 million carats of diamond at a rate of 6 million carats per year worth about $63 per carat (Diavik Diamond Mines Inc., 2000, p. 10-12).

- "Conflict diamonds" continued to partially finance warfare in Angola, Congo (Kinshasa), and Sierra Leone. In 2000, these "conflict diamonds" were discussed in the United Nations (U.N.), the U.S. Congress, the World Diamond Council, and the news media. The U.N. adopted a resolution on the role of diamonds in fueling conflict. A bill that was introduced, but not passed, in the 106th U.S. Congress would have required jewelry retailers to reveal the country of origin for all diamonds sold in the United States. In 2001, a revised version of this bill was reintroduced in the 107th U.S. Congress. The revised bill calls for a comprehensive diamond certification program and says that the United States can only import rough diamond from countries with the proper controls to ensure against importation of "conflict diamonds." "Conflict diamonds" were also the subject of much television and other media coverage in 2000. Despite all of this discussion and media attention, surveys indicate that during 2000, most diamond jewelry consumers did not ask for the country of origin when making their diamond buying decisions (Diamond Registry Bulletin, 2000a). One survey in 2000 indicated that 93% of consumers who were surveyed had never heard of "conflict diamonds," but 76% of consumers said that they would not purchase diamonds or diamond jewelry knowing that it came from a country where social injustice had occurred as a result of its production (Diamond Registry Bulletin, 2000c).
- De Beers Canada Mining Inc. acquired the Snap Lake diamond project from Winspear Diamonds Inc. and Aber Diamond Corp. in 2000. Snap Lake is located in the Northwest Territories and will be De Beers' first mine outside of southern Africa and the first underground diamond mine in Canada. Snap Lake has estimated reserves of 22.8 Mt of ore in a kimberlite dike, containing 38.8 million carats of diamonds, and the mine life is projected to be 20 years or more. Snap Lake is in its development phase and is scheduled to begin diamond production in the first half of 2003 (De Beers Canada Mining Inc., 2000, Snap Lake diamond project fact sheet, accessed June 13, 2001, at URL http://www.debeerscanada.com/files_new/snap/infrastruct.html).
- E-commerce in diamond and gemstone jewelry continued to grow during 2000. While more jewelry websites started operating online, many of the dot-com businesses overspent on advertizing and went out of business as a result. Preholiday season surveys indicated that the vast majority of 1999 online holiday customers also shopped online in 2000, and they spent more. The entire sum of online holiday sales, however, only amounted to about 1.5% of overall retail jewelry sales in 2000 (Diamond Registry Bulletin, 2000b).

Worldwide production of natural gemstones other than diamond was estimated to have exceeded $2 billion per year in the late 1990s. Most nondiamond gemstone mines are small, low-cost, and widely dispersed operations in remote regions of developing nations. Foreign countries with major gemstone deposits other than diamond are Afghanistan (beryl, ruby, and tourmaline); Australia (beryl, opal, and sapphire); Brazil (agate, amethyst, beryl, ruby, sapphire, topaz, and tourmaline); Burma (beryl, jade, ruby, sapphire, and topaz); Colombia (beryl, emerald, and sapphire); Kenya (beryl, garnet, and sapphire); Madagascar (beryl, rose quartz, sapphire, and tourmaline); Mexico (agate, opal, and topaz); Sri Lanka (beryl, ruby, sapphire, and topaz); Tanzania (garnet, ruby, sapphire, tanzanite, and tourmaline); and Zambia (amethyst and beryl). In addition, pearls are cultured throughout the South Pacific and in other equatorial waters; Australia, China, French Polynesia, and Japan are key producers.

Colored gemstone producers continued their recovery from the weakened markets created by the Asian economic crisis of 1997-98. Mining and sales reportedly were disrupted in many nations, particularly in Southeast Asia. Prices of high-quality colored gemstones, however, did not decline dramatically (Cavey, 1998).

Additional noteworthy items in the colored gemstone industry during 2000 included the following:

- Owing to the increased misuse of the terms like "synthetic" and "laboratory-created" in deceptive advertizing and owing to the proliferation of treatment processes to enhance gemstone attributes artificially without disclosure, the Federal Trade Commission has modified its "Guides for the Jewelry, Precious Metals, and Pewter Industries." The modified regulations went into effect April 10, 2001.
- During 2000, the popularity of colorful gemstones, colored synthetic gemstones, and "fancy" colored diamonds (even black diamonds) increased, as was evidenced by increased sales that are expected to continue in 2001 (Jewelers' Circular Keystone, 2000; Jewellery News Asia, 2000a, 2000c, 2001).

Outlook

It appears that the 2001 U.S. economy will not be a continuation of the good times we have enjoyed for the last few years. The U.S. diamond industry can take comfort in the fact that the value of their inventory is holding much better than the stock market (Diamond Registry Bulletin, 2001b). Historically, diamonds have proven to hold their value despite wars or depressions in the economy (Schumann, 1998, p. 8).

Diamond exploration is continuing in Canada, and many new deposits are being found. There have been additional discoveries in both the core and buffer zones of the Ekati lease. At least 35 kimberlites have been discovered in north-central Alberta, 70 large kimberlites have been found in Saskatchewan, and additional discoveries have been made in Ontario and Quebec (Luc Rombouts, Terraconsult bvba, May 2, 2001, Diamond annual review—2000, accessed June 19, 2001, at URL http://www.terraconsult.be/overview.htm). When the Diavik and Snap Lake mines begin production, Canada will be producing at least 15% to 20% of the total world diamond production.

Independent producers, such as Argyle Diamond Mines in Australia and new mines in Canada, will continue to bring a greater measure of competition to global markets. More competition presumably will bring more supplies and lower prices.

Numerous synthetics, simulants, and treated gemstones will enter the marketplace and necessitate more transparent trade

Digitized by Google

industry standards to maintain customer confidence.

More diamonds, gemstones, and jewelry will be sold through online marketplaces and other forms of e-commerce that emerge to serve the diamond and gemstone industry. This will take place as the industry and its customers become more comfortable with and learn the best applications of new e-commerce tools for the gemstone industry (Authority on Jewelry Manufacturing, 2001).

TABLE 1
GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size 1/	Cost 2/	Mohs	Specific gravity	Refraction	Refractive index	May be confused with	Recognition characters
Amber	Hydrocarbon	Yellow, red, green, blue	Any	Low to medium	2.0-2.5	1.0-1.1	Single	1.54	Synthetic or pressed plastics	Fossil resin, soft.
Benitoite	Barium titanium silicate	Blue, purple, pink, colorless	Small to medium	High	6.0-6.5	3.64-3.68	Double	1.76-1.80	Sapphire, tanzanite, blue diamond, blue tourmaline	Strong blue in ultraviolet light.
Beryl:										
Aquamarine	Beryllium aluminum silicate	Blue-green to light blue	Any	Medium to high	7.5-8.0	2.63-2.80	do.	1.58	Synthetic spinel, blue topaz	Double refraction, refractive index.
Bixbite	do.	do.	Small	Very high	7.5-8.0	2.63-2.80	do.	1.58	Pressed plastics, tourmaline	Refractive index.
Emerald	do.	Green	Medium	do.	7.5	2.63-2.80	do.	1.58	Fused emerald, glass, tourmaline, peridot, green garnet doublets	Emerald filter, dichroism, refractive index.
Emerald, synthetic	do.	do.	Small	High	7.5-8.0	2.63-2.80	do.	1.58	Genuine emerald	Flaws, brilliant, fluorescence in ultraviolet light.
Golden (heliodor)	do.	Yellow to golden	Any	Low to medium	7.5-8.0	2.63-2.80	do.	1.58	Citrine, topaz, glass, doublets	Weak-colored.
Goshenite	do.	do.	do.	Low	7.5-8.0	2.63-2.80	do.	1.58	Quartz, glass, white sapphire, white topaz	Refractive index.
Morganite	do.	Pink to rose	do.	do.	7.5-8.0	2.63-2.80	do.	1.58	Kunzite, tourmaline, pink sapphire	Do.
Calcite:										
Marble	Calcium carbonate	White, pink, red, blue, green, or brown	do.	do.	3.0	2.72	Double (strong)	1.49-1.66	Silicates, banded agate, alabaster gypsum	Translucent.
Mexican onyx	do.	do.	do.	do.	3.0	2.72	do.	1.60	do.	Banded, translucent.
Chrysoberyl:										
Alexandrite	Beryllium aluminate	Green by day, red by artificial light	Small (former U.S.S.R.)	High	8.5	3.50-3.84	Double	1.75	Synthetic	Dichroism, inclusions in synthetic sapphire.
Do.	do.	do.	Medium (Sri Lanka)	do.	8.5	3.50-3.84	do.	1.75	do.	Do.
Cats-eye	do.	Greenish to brownish	Small to large	do.	8.5	3.50-3.84	do.	1.75	Synthetic, shell	Gravity and translucence.
Chrysolite	do.	Yellow, green, and/or brown	Medium	Medium	8.5	3.50-3.84	do.	1.75	Tourmaline, peridot	Refractive index, silky.
Coral	Calcium carbonate	Orange, red, white, black, or green	Branching, medium	Low	3.5-4.0	2.6-2.7	do.	1.49-1.66	False coral	Dull translucent.
Corundum:										
Ruby	Aluminum oxide	Rose to deep purplish red	Small	Very high	9.0	3.95-4.10	do.	1.78	Synthetics, including spinel	Inclusions, fluorescence.
Sapphire	do.	Blue	Medium	High	9.0	3.95-4.10	do.	1.78	do.	Inclusions, double refraction, dichroism.
Sapphire, fancy	do.	Yellow, pink, white, orange, green, or violet	Medium to large	Medium	9.0	3.95-4.10	do.	1.78	Synthetics, glass and doublets	Inclusions, double refraction, refractive index.
Sapphire and ruby, stars	do.	Red, pink, violet, blue, or gray	do.	High to low	9.0	3.95-4.10	do.	1.78	Star quartz, synthetic stars	Shows asterism, color side view.

TABLE 1—Continued
GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size 1/	Cost 2/	Mohs	Specific gravity	Refraction	Refractive index	May be confused with	Recognition characters
Corundum:										
Sapphire or ruby, synthetic	Aluminum oxide	Yellow, pink, or blue	Up to 20 carats	Low	9.0	3.95-4.10	Double	1.78	Synthetic spinel, glass	Curved striae, bubble inclusions.
Diamond	Carbon	White, blue-white, yellow, brown, green, pink, blue	Any	Very high	10.0	3.516-3.525	Single	2.42	Zircon, titania, cubic zirconia	High index, dispersion, hardness, luster.
Feldspar:										
Amazonite	Alkali aluminum silicate	Green	Large	Low	6.0-6.5	2.56	XX	1.52	Jade	Cleavage, sheen, vitreous to pearly, opaque, grid.
Labradorite	do.	Gray with blue and bronze sheen color play	do.	do.	6.0-6.5	2.56	XX	1.56	do.	Do.
Moonstone	do.	Colorless or yellow	do.	do.	6.0-6.5	2.77	XX	1.52-1.54	Glass	Pale sheen, opalescent.
Garnet	Complex silicate	Brown, black, yellow, green, ruby red, or orange	Small to medium	Low to high	6.5-7.5	3.15-4.30	Single strained	1.79-1.98	Synthetics, spinel, glass	Single refraction, anomalous strain.
Jade:										
Jadeite	do.	Green, yellow, black, white, or mauve	Large	Low to very high	6.5-7.0	3.3-3.5	Crypto-crystalline	1.65-1.68	Onyx, bowenite, vesuvianite, grossularite	Luster, spectrum, translucent, to opaque.
Nephrite	Complex hydrous silicate	do.	do.	do.	6.0-6.5	2.96-3.10	do.	1.61-1.63	do.	Do.
Opal	Hydrous silica	Colors flash in white gray, black, red, or yellow	do.	Low to high	5.5-6.5	1.9-2.3	Single	1.45	Glass, synthetics, triplets	Play of color.
Pearl	Calcium carbonate	White, pink, or black	Small	do.	2.5-4.0	2.6-2.85	XX	XX	Cultured and imitation	Luster, structure, x ray.
Peridot	Iron magnesium silicate	Yellow and/or green	Any	Medium	6.5-7.0	3.27-3.37	Double (strong)	1.65-1.69	Tourmaline chrysoberyl	Strong double refraction, low dichroism.
Quartz:										
Agate	Silica	Any	Large	Low	7.0	2.58-2.64	XX	XX	Glass, plastic, Mexican onyx	Cryptocrystalline, irregularly banded, dendritic inclusions.
Amethyst	do.	Purple	do.	Medium	7.0	2.65-2.66	Double	1.55	do.	Refractive index, double refraction, transparent.
Cairngorm	do.	Smoky orange or yellow	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Citrine	do.	Yellow	do.	do.	7.0	2.65-2.66	do.	1.55	do.	Do.
Crystal, rock	do.	Colorless	do.	do.	7.0	2.65-2.66	do.	1.55	do.	Do.
Jasper	do.	Any, striped, spotted, or sometimes uniform	do.	do.	7.0	2.58-2.66	XX	XX	do.	Opaque, vitreous.
Onyx	do.	Many colors	do.	do.	7.0	2.58-2.64	XX	XX	do.	Uniformly banded.
Rose	do.	Pink, rose red	do.	do.	7.0	2.65-2.66	Double	1.55	do.	Refractive index, double refraction, translucent.
Spinel	Magnesium aluminum oxide	Any	Small to medium	Medium	8.0	3.5-3.7	Single	1.72	Synthetic, garnet	Refractive index, single refraction, inclusions.
Spinel, synthetic	do.	do.	Up to 40 carats	Low	8.0	3.5-3.7	Double	1.73	Spinel, corundum, beryl, topaz, alexandrite	Weak double refraction, curved striae, bubbles.

TABLE 1—Continued
GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size 1/	Cost 2/	Mohs	Specific gravity	Refraction	Refractive index	May be confused with	Recognition characters
Spodumene:										
Hiddenite	Lithium aluminum silicate	Yellow to green	Medium	Medium	6.5-7.0	3.13-3.20	do.	1.66	Synthetic spinel	Refractive index.
Kunzite	do.	Pink to lilac	do.	do.	6.5-7.0	3.13-3.20	do.	1.66	Amethyst, morganite	Do.
Tanzanite	Complex silicate	Blue	Small	High	6.0-7.0	3.30	Double	1.69	Sapphire, synthetics	Strong trichroism.
Topaz	do.	White, blue, green	Medium	Low to medium	8.0	3.4-3.6	do.	1.62	Beryl, quartz	Refractive index.
Tourmaline	do.	Any, including mixed	do.	do.	7.0-7.5	2.98-3.20	do.	1.63	Peridot, beryl, corundum, glass	Double refraction, refractive index.
Turquoise	Copper aluminum phosphate	Blue to green	Large	Low	6.0	2.60-2.83	do.	1.63	Glass, plastics	Difficult if matrix not present, matrix usually limonitic.
Zircon	Zirconium silicate	White, blue, or brown, yellow, or green	Small to medium	Low to medium	6.0-7.5	4.0-4.8	Double (strong)	1.79-1.98	Diamond, synthetics, topaz, aquamarine	Double refraction, strongly dichroic, wear on facet edges.

XX Not applicable.
1/ Small: up to 5 carats; medium: 5 to 50 carats; large: more than 50 carats.
2/ Low: up to $25 per carat; medium: up to $200 per carat; high: more than $200 per carat.

GERMANIUM

By Robert D. Brown, Jr.

Domestic survey data and tables were prepared by Carolyn F. Crews, statistical assistant.

Germanium, a grayish-white element, is a semiconductor, with electrical characteristics between those of a metal and an insulator. It is commercially available as a tetrachloride and a high-purity oxide and in the form of metal ingots, single-crystal bars, castings, doped semiconductors, optical materials, optical blanks, and other specialty products. Germanium is used principally in fiber optics, infrared optics, and polymerization catalysts. Its special mechanical, optical, and electrical properties, as well as its moderate cost, also make it attractive in many aerospace applications.

In 2000, the domestic germanium industry consisted of two zinc mining operations in Alaska and Tennessee, which supplied byproduct germanium concentrates for export, and three refineries in New York, Oklahoma, and Pennsylvania. The domestic refineries processed manufacturers' scrap, imported semirefined materials, and some old (postconsumer) scrap. Domestic refinery production, which amounted to slightly less than one-third of world refinery output, was estimated to be valued at $29 million. Domestic refinery production and consumption for germanium are estimated by the U.S. Geological Survey (USGS) on the basis of discussions with domestic producers. Both domestic refinery production and U.S. consumption of germanium were estimated to have increased in 2000.

The USGS estimated domestic germanium reserves to be 450,000 kilograms (kg), equivalent to 15 years of domestic consumption at the 2000 rate; figures for worldwide reserves were not available. Worldwide, germanium resources are associated with zinc and lead-zinc-copper sulfide ores.

As a strategic and critical material, germanium was included in the National Defense Stockpile (NDS) in 1984, with an initial goal of 30,000 kg of germanium metal. In 1987, a new NDS goal of 146,000 kg was established; in 1991, this was adjusted downward to 68,198 kg. In 1995, the Defense Logistics Agency (DLA), which maintains the NDS, made plans to sell germanium at a rate of 4,000 kilograms per year (kg/yr) through 2005. This proposed rate remained the same for 1996, but it was increased to 6,000 kg/yr in 1997 and to 8,000 kg/yr in 1998. All the material offered is zone-refined polycrystalline germanium metal (U.S. Department of Defense, 1997). The amount designated for annual sales was a significant portion of the domestic and world market, but in most years less than the amount available for sale has been sold.

At the current stockpile disposal rate, the DLA price has become not only a good indicator of the market value of germanium, but also a factor in determining that value. Sales began in 2000 at just under $1,000 per kilogram and fell gradually to $870 per kilogram during the year (Mining Journal, 2000b). After 2,843 kg was sold in 2000, the yearend inventory was 48,531 kg of germanium metal. The main factor resulting in the price decrease was a continued slowdown in the implementation of satellite communication systems in spite of brisk demand in other use sectors.

Production

In 2000, the USGS estimated U.S. refinery production of germanium from primary and semirefined materials to be 23,000 kg, 15% more than that of 1999. The Electro-Optic Materials Department of Eagle-Picher Industries, Inc., in Quapaw, OK, remained the largest domestic producer in 2000, producing germanium from reprocessed scrap, fly ash, germanium concentrates (typically containing 5% or more germanium), and semirefined germanium materials.

Cabot Corp., Revere, PA, and Atomergic Chemetals Corp., Plainview, NY, produced germanium from reprocessed scrap and semirefined foreign material. The zinc refinery at Clarksville, TN, owned by Savage Resources Ltd., continued to produce germanium-rich residues as a byproduct of processing zinc ores from its associated Elmwood-Gordonsville Mine. Savage has continued the established practice of shipping these residues to Union Minière, SA's Electro-Optic Materials Business Unit in Belgium for germanium recovery and refining.

Consumption

The USGS estimates that domestic consumption of germanium in 2000 increased to approximately 28,000 kg. The domestic use pattern was similar to the world use pattern, which was estimated to be as follows: fiber optics, 50%; polymerization catalysts, 25%; infrared optics, 15%; electrical/solar applications, 5%; and other uses (as phosphors, in metallurgy, and in chemotherapy), 5%. The major difference between the domestic and world patterns of consumption is that the greatest U.S. germanium demand is for fiber optics, while in Japan most of the germanium is used for polymerization catalysts (Roskill's Letter from Japan, 1999).

In the fiber optics sector, germanium was used as a dopant within the core of optical fiber used by the telecommunications industry. Because germanium lenses and windows are transparent to infrared radiation, they can be used in infrared optical systems in the same ways that ordinary glass lenses and windows are used in visible light optical systems. These optics have been used principally for military guidance and weapon-sighting applications. Germanium glass was also used for nonmilitary surveillance, night vision, and monitoring systems in a wide range of fields, including satellite systems and fire alarms.

A significant factor influencing germanium consumption in 2000 involved satellite communication systems. Satellite launch delays at the Teledesic Project, which is to be a large satellite based communications system, resulted in a decline in solar cell manufacture. This project, when restarted, would require about 12,000 kg of germanium for solar cells (Mining Journal, 2000a). The decline in consumption for solar cell applications was overcome by increases in other sectors in 2000. The use of germanium as a dopant in optical fibers continued to grow.

Digitized by Google

General Motors Corp. began incorporating a germanium-based night vision system in its top-of-the-line cars. Several manufacturers have begun production of SiGe chips.

Prices

In 1995, domestic producer prices for germanium metal and dioxide were, for the first time, set higher than the longstanding price levels established in late 1981 ($1,060 and $660 per kilogram, respectively). Throughout the 1981-1995 period, producers significantly discounted prices in response to competition from imported materials. In 1995 and 1996, however, producer prices for zone refined metal reportedly reached $1,375 and $2,000 per kilogram, respectively; germanium dioxide producer prices rose to $880 and $1,300 per kilogram, respectively. In 1997, the producer prices fell back to $1,475 per kilogram for the metal and $950 per kilogram for the dioxide. In 1998, they increased again to $1,700 per kilogram for the metal and $1,100 per kilogram for the dioxide. In 1999, the prices were reduced to $1,400 and $900 per kilogram, respectively, owing to sluggish demand. In 2000, prices continued to fall, reaching $1,250 and $800 per kilogram, respectively, mainly due to plentiful supply rather than lack of demand.

Free market prices for germanium dioxide, published by Metal Bulletin, began 2000 in the $680 to $750 per kilogram range and ended the year in the $620 to $700 range. The price for Belgian-produced germanium dioxide, published by Metal Bulletin, remained at $750 per kilogram all year.

In 1998, germanium prices increased despite an oversupply that resulted from: (1) slight decreases in world demand for optical fibers and polyethylene terephthalate (PET); and (2) an increase in total supply owing to greater amounts of recycling and continued releases of germanium from national stockpiles in Russia, Ukraine, and the United States. This increase in price was probably due to anticipated demand in the satellite communications sector, and, when this increase in demand did not occur in 1999, germanium prices began to fall. This same mechanism prevailed in 2000. Demand in satellite applications did not increase, and prices continued to fall.

Trade

In 2000, the estimated germanium content of imports was approximately 8,210 kg, compared with 12,400 kg in 1999. China, Belgium, and Russia, in descending order of shipments, accounted for approximately 87% of U.S. germanium imports in 2000 (table 1). Imports directly attributable to China and countries of the former Soviet Union amounted to about 53% of the total. Trade reliance on large shipments from these countries began in the early 1990s.

World Review

In 2000, world refinery production of primary germanium was estimated to be slightly more than 70,000 kg, an increase of more than 20% from that of 1999. Recycling supplied 25,000 kg of germanium worldwide, the same as in 1999. The world total market supply was about 105,000 kg in 2000, counting 3,000 kg released from the U.S. NDS and 6,000 kg taken from non-Government stockpiles. World consumption matched the total supply. This exceeded production, but supply was made adequate owing to the amounts gained from recycling and stockpile releases. World consumption for 2000 was 19% higher than that in 1999.

Austria.—Austria Mikro Systeme International AG is constructing a modern facility for the production of application-specific integrated circuits and application-specific standard products, including silicon-germanium devices. These products will be for automotive, communication, and industrial applications. The budget for the construction of the new production line is 305 million euro (Austria Mikro Systeme International AG, 2000).

Belgium.—Union Minière, SA, Brussels, made nearly $16 million profit when it sold its share of EMCORE Corp., a semiconductor technology company with headquarters in Somerset, NJ. A joint venture between the two companies to develop new applications for germanium-based components and supply germanium substrates for space solar cells will continue (American Metal Market Online, March 3, 2000, UM posts profit on EMCORE stake sale, accessed March 17, 2000, via URL http://www.AMM.com).

China.—The Nei Mongol Coalfield Geology Bureau has discovered a large germanium deposit at Xilinhaote in Nei Mongol. The germanium contained in the deposit is estimated to be up to 1,600 metric tons, which would make it account for 30% of China's reserves. It is a paragenetic coal/germanium deposit, the largest in China. It would be amenable to large scale open pit mining (Engineering and Mining Journal, 1999). China is the leading supplier of germanium to the United States, accounting for 42% of germanium imports in 1999 and 40% in 2000. China is also a leading supplier of germanium oxide to Japan for use in the production of PET bottles. China provided more than one third of Japanese imported germanium oxide in 1999.

Germany—PPM Pure Metals AG, a subsidiary of Metaleurop GmbH, produces many high-purity metals and compounds including germanium oxide for use as a polymerization catalyst in the production of PET polymer and as a reflective dopant in the core of optical fibers. The company expects to grow with the expanding germanium market (Karpel, 2000).

Current Research and Technology

Germanium is being used for the optics in night vision systems that utilize infrared rays. The germanium lens focuses the infrared rays from the object observed to a detector. All objects emit heat to some degree, but humans, animals, and moving vehicles are quite visible in the infrared spectrum because of the large contrast of emission from the object compared to its background. General Motors installed these systems called night vision, manufactured by Raytheon Corp., on its Cadillac DeVille model in 2000 (Siuru, 1999). Cadillac predicted sales of 3,500 units in 2000, but then asked Raytheon to quadruple production. In its first year, 7,000 of the night vision systems were installed, with Cadillac dealers demanding more. It is expected that production will double again in 2001. Currently the device adds about $2,000 to the cost of the DeVille. High-volume production could cut the cost in half (Truett, 2001). The night vision segment of the surveillance market is expected to grow from $560 million in 1999 to $750 million by 2004 (Hindus, 2000).

Digitized by Google

Silicon-germanium (SiGe) technology is poised for growth. With the proven viability of implanting silicon with germanium to produce transistors, a number of manufacturers have begun production (Bindra, 2000). By depositing a layer of germanium onto the silicon, one can engineer the energy band structure, the band gap, electron mobilities, and numerous other properties while using conventional silicon processing (Paul, 2000). The only additional step is the actual deposition of the germanium. The cost of this kind of processing is proportional to the number of steps; since 10 to 30 steps are typically involved in the fabrication of a chip, however, the one extra step increases the cost very little (Pool, 2001). SiGe chips combine the high speed properties of germanium with the low cost, well established production techniques of the silicon-chip industry. Most semiconductor technologies that use more than one material are complicated because of the physical and chemical differences between the components. Because silicon and germanium are fairly similar, SiGe processing can be relatively simple.

SiGe also requires less power to perform the same function as its silicon counterpart (Pool, 2001). Thus, SiGe has great potential for mobile phone applications because talk time or battery life is very important in wireless communication. SiGe is expected to provide faster, smaller, and cheaper microchips for third generation mobile phones (Pool, 2001). Gallium arsenide also may be vulnerable to substitution by SiGe in microwave devices (Metal Bulletin, 2000). Strategies Unlimited, a market analysis firm, has predicted that the market for SiGe wireless and digital applications will reach $1.8 billion by 2005 (Paul, 2000).

Outlook

Expected demand increases for fiber optics and new uses could fuel a drive for the development of new germanium resources. The industry appears poised for expansion in spite of recent lackluster price performance (Karpel, 2000). Balancing mechanisms of stockpile releases and increased recycling have thus far tended to hold prices down in spite of increasing demand. Further, even significant increases in demand do not drive prices up if these increases are somewhat less than expected. Greater volatility in the germanium market, however, could occur during the next few years if stockpiles and recycling cannot adequately balance supply and rising demand.

GOLD

By Earle B. Amey

Domestic survey data and tables were prepared by Mahbood Mahdavi, statistical assistant, and the world production table was prepared by Ronald L. Hatch, lead international data coordinator.

Domestic gold mine production in 2000 was midway between the alltime high record reached in 1998 and what was produced in 1999. Primarily, the 3.5% improvement over the 1999 level was the result of more stable gold prices and the weakening of the United States dollar. The United States has been the second largest gold producer (behind South Africa) since 1991, when U.S. production surpassed that of the Soviet Union for the first time in five decades. Nevada produced more than three-fourths of domestic production; the remaining output came from 10 other States. Gold was produced at 64 lode mines; about a dozen large placer mines, all in Alaska; and numerous small placer mines, mostly in Alaska and the Western States. In addition, a small amount of domestic gold was produced as a byproduct of processing base metals, principally copper. Thirty mines yielded almost 97% of the gold produced in the United States. The value of U.S. gold mine production was about $3.2 billion in 2000.

Domestic gold exploration activity dropped on a total dollar basis for the third consecutive year, declining from $194.5 million in 1999 to $183.4 million in 2000. The percentage of the total world gold exploration budget going to the United States, however, increased by 16.8% in 2000 for the third time because U.S. companies spent proportionately more on gold as worldwide gold exploration expenditures dropped by 7% from 1999, by 24% from 1998, and by 29% from 1997 (diGesu and others, 2000b).

Commercial-grade refined gold came from about two dozen domestic producers. Of several thousand companies and artisans, a few dozen companies dominated the fabrication of gold into commercial products. U.S. jewelry manufacturing was heavily concentrated in the New York, NY, and the Providence, RI, areas, with other concentrations in California, Florida, and Texas. In 2000, estimated end uses of gold were jewelry and arts, 89%; dental, 7%; and electrical and electronics, 4%. According to the World Gold Council (2001, p. 2), 2000 was the 10th consecutive year of unit sales increases for gold jewelry in the United States. Total U.S. gold jewelry sales exceeded $15 billion, up by 4% from sales in 1999.

Trade in refined bullion comprised 82.5% of U.S. gold imports and 80% of exports; net exports of bullion rose to 256,000 kilograms (kg), up by more than 7% from that of 1999. As shown in tables 4 and 6, Canada provided about 60% of the bullion imported, and Switzerland was the destination for more than 60% of the bullion exported.

The dollar price for gold was volatile in 2000, but prices by yearend were only slightly lower than gold prices at the beginning of the year. Engelhard Corp.'s daily price of gold ranged from a low of nearly $265 per troy ounce[1] on October 27 to a high of about $314 on February 7. The average for the year was, to the nearest dollar, $280. The previous year's prices ranged from about $254 to $327 and averaged $280.

By the third quarter, 12-month London gold lease rates

[1]Elsewhere in this report, ounce by itself refers to troy ounce; 1 kilogram is equivalent to 32.1507 troy ounces.

Gold in the 20th Century

In 1900, the United States led the world in gold production with an output of 119 kilograms of gold, accounting for about 31% of total world production, followed by Australia, Canada, and Russia. A hundred years ago, no gold was produced in South Africa, which is the largest producer of gold today. Colorado was the largest gold-producing State in the United States, providing about 36% of total U.S. gold output. Nevada, which is the leading domestic gold-producing State today, produced only 3% of the total U.S. output in 1900, but would benefit greatly from cyanide-heap leach technology to extract gold from its low-grade gold ores in the late 1960s. The major uses of gold in the early 1900s were for jewelry and monetary investments. At the opening of the 20th century, the official price of gold was $20.67 per troy ounce and Congress passed the Gold Standard Act of 1900, which confirmed the gold dollar as the standard unit of monetary value, with the value of $1 set at 25.8 grains of 900 fine gold. During the First and Second World Wars, the international gold standard was suspended by the combatant but restored following cessation of hostilities. During the Great Depression, exports of gold except under Government license were prohibited, and all gold and gold certificates were recalled from general circulation. In 1934, silver was brought back as a standard unit of monetary value, and the gold content of the gold dollar was reduced to 13.7 grains of 900 fine gold.

In 2000, the United States was the second largest gold-producing country with an output of about 353 kilograms of gold accounting for about 14% of the total world output. South Africa ranked first and Australia, China, and Canada ranked third, fourth, and fifth respectively, in global gold output. Nevada produced three-fourths of U.S. gold, while Colorado produced less than 3% of the total domestic output. Over 85% of today's domestic gold is used for jewelry and arts with most of the remainder used as low-resistance electrical conductors. The price of gold in 2000 averaged $280 per troy ounce, which is about 14 times greater than the price of gold in 1900.

Digitized by Google

dropped from about 1.6% in January to 1.2% in October and remained the same through December. Short-term lease rates decreased from historic lows of 0.5% in January to less than 0.3% in August before rising to 0.7% in December (CRU International Ltd., 2001).

Total world mine production of gold was about the same as the record level reached in 1999. Despite a sixth successive decline in annual output, South Africa remained the largest producer of more than 80 gold-mining nations, followed by the United States, Australia, China, and Canada. Identified world gold resources at yearend 1999 were estimated to be 100 million kilograms (Mkg), of which 15% to 20% were byproduct resources; the world reserve base was estimated to be 73 Mkg, and reserves, 48 Mkg (R.P. Ashley, U.S. Geological Survey, oral commun., 2000). [This report uses the resource and reserve terminology of the U.S. Geological Survey (USGS), which is republished annually in USGS Mineral Commodity Summaries (U.S. Bureau of Mines and U.S. Geological Survey, 1980).] South Africa had about 50% of the resources, 50% of the reserve base, and 38% of the reserves. The United States had about 9% of world resources, 8% of the reserve base, and 12% of the reserves.

About 15% of all gold mined is estimated to have been used in dissipative industrial uses, or is either unaccounted for or unrecoverable (Thomas and Boyle, 1986, p. 6). Therefore, of an estimated 140 Mkg of gold mined in historical times through 2000, 119 Mkg of gold remain, with about 33 Mkg held by central banks as official stocks and about 78 Mkg held privately as bullion, coin, and jewelry.

The USGS has issued a report on undiscovered gold, silver, copper, lead, and zinc deposits in the United States (U.S. Geological Survey, 2000). In the report, the amount of gold in undiscovered U.S. mineral deposits is estimated to range between greater than 13 Mkg (90% probability) and greater than 22 Mkg (10% probability). The mean value of gold in the undiscovered deposits is 18 Mkg with nearly one-quarter of the gold estimated to be contained in undiscovered porphyry copper deposits. Other major gold deposit types considered in the report were hot spring gold, epithermal vein, plutonic porphyry gold, sediment-hosted gold, Au-Ag-Te veins, and low-sulfide gold-quartz vein deposits. Total discovered gold resources in the United States were estimated to be 27 Mkg; identified U.S. gold resources were estimated to be 15 Mkg and all U.S. gold production was 12 Mkg.

Production

Domestic mine production data for gold were derived by the USGS from two separate voluntary surveys of U.S. operations—one for monthly production of copper, gold, lead, silver, and zinc from lode mines and the other for the same types of data from companies that responded annually.

Of the 77 lode gold producers in operation to which a survey request was sent, 75 responded. Thirteen of the 75 responses reported that their mines were closed and another 6 remained on care-and-maintenance status by the end of 2000. The individual company production and performance data in table 3 and cited elsewhere in this report were obtained from published sources, such as company annual reports.

Of the total domestic gold produced during 2000, about 93% was extracted from gold ore, and the remaining 7% was derived from other precious-metal ores, base-metal ores, and placer deposits. By comparison, similar data assembled for 1980 indicated a 63% to 37% ratio. In both years, the contribution from placer mines amounted to less than 2% of the total gold produced.

Alaska.—The State's Division of Geology and Geophysical Surveys reported that gold output decreased to 15,600 kg (501,000 ounces) worth $140 million in 2000 from an estimated 16,100 kg (518,000 ounces) worth $144 million in 1999, or an approximate decrease in production of 3% and a decrease in associated value of about 3% (Szumigala and Swainbank, 2001). Placer production dropped to 1,300 kg (41,000 ounces) from 1,700 kg (56,000 ounces) of gold.

The underground Fort Knox gold mine near Fairbanks began to produce gold in 1997. Kinross Gold Corp. reported that the mine produced about 11,300 kg (363,000 ounces) of gold in 2000, making it the country's ninth largest gold producer (Kinross Gold Corp., 2001, p. 24).

The Greens Creek Mine on Admiralty Island, off Juneau, completed its fourth year at full production levels. Ore from the underground trackless mine was milled at the mine site. The mill produced gold and silver doré, lead, zinc, and bulk concentrates. Hecla Mining Co. reported (2001, p. 7) that the mine produced 2,600 kg (83,700 ounces) of gold. Greens Creek was a joint venture between Kennecott Greens Creek Mining Co. (70.3%) and Hecla Mining (29.7%).

USMX Inc.'s Illinois Creek gold mine in west-central Alaska was placed on care and maintenance, but continued to produce gold as the existing heaps were rinsed (Szumigala and Swainbank, 2001).

Continued drilling at the Pogo joint venture between Teck Corp. and Sumitomo Metal Mining America Inc. defined new gold ore zones in the eastern interior region (Wilburn, 2001, p. 49).

California.—Gold production in California remained about the same as that of 1999, as shown in table 2. California's largest gold mine, Newmont Gold Co.'s Mesquite Mine, near Brawley, yielded more than 4,100 kg (130,000 ounces) of gold from oxide and sulfide ores that were mined by open pit methods (Newmont Gold Co., 2001, p. 53).

In eastern Imperial County, Glamis Gold Ltd. continued to produce gold by using heap-leaching methods at its Picacho Mine and continued exploration at its nearby Imperial project. Picacho produced about 45 kg (1,400 ounces). In 1997, after 16 years of gold production, reserves were exhausted, and mining ceased. Gold recovery from the last ore heap was expected to take another year, after which reclamation will begin. Glamis Gold, through its wholly owned Glamis Rand Mining Co., also produced 3,100 kg (100,000 ounces) of gold at its Rand Mine near Randsburg. Almost all mining at the Rand Mine was carried out at the Yellow Aster Pit (Glamis Gold Ltd., 2001, p. 2).

Near the Nevada-California State line, in San Bernardino County, the Castle Mountain Mine produced an estimated 3,700 kg (119,000 ounces) of gold (Viceroy Resource Corp., 2001, p. 2). Castle Mountain was a joint venture between Viceroy Resource Corp. (75%) and MK Gold Co. (25%).

Colorado.—Gold production in the State was 7% higher with a significant increase in production from the Nation's 11th largest gold mine, the Cresson Mine, in the Cripple Creek District of Teller County. AngloGold Ltd. reported (2001, p.

Digitized by Google

20) that this open pit mining operation produced 7,700 kg (248,000 ounces) of gold in 2000.

Idaho.—Meridian Gold Inc.'s closure of its Beartrack Mine near Salmon leaves Idaho with no active gold mines. Beartrack produced more than 2,250 kg (73,000 ounces) of gold in 2000 about 45% less than in 1999. Leaching of crushed ore is expected to continue to produce gold over the next several years on a declining basis (Meridian Gold Inc., 2001).

Montana.—Exploration for gold was continued at an extremely low level, funded by a few venture capital dollars. No major mining companies were known to be involved. Low gold prices during the year and market limitations targeted interest toward gold with investment potential, such as free-milling gold and gold placers (McCulloch, 2001, p. 82).

Placer Dome Inc.'s wholly owned Golden Sunlight Mine near Whitehall was Montana's largest gold-producing mine with 6,600 kg (212,300 ounces) of gold in 2000, about 47% more than in 1999 (Placer Dome Inc., 2001, p. 10).

Nevada.—Nevada maintained its longstanding position as the Nation's dominant gold-producing State. Of the Nation's top 30 gold-producing mines, 15 were in the Silver State. Primary gold production increased to 268,000 kg (8.6 million ounces).

Newmont Gold, the largest gold mining company in North America, produced 94,000 kg (3.0 million ounces) of gold from 9 open pit operations, 4 underground mines, and 17 processing facilities in Elko, Eureka, Humboldt, and Pershing Counties. Newmont Gold marked 35 years of production on the Carlin Trend, which it discovered in the mid-1960s. Mining of the high-grade Deep Post pit deposit concluded at the end of 2000, while gold production from stockpiles will continue into early 2001. With reserves of 93,000 kg (3.0 million ounces) of gold, Deep Post consists of both a surface zone, currently being mined within the Betze-Post Pit, and a deeper zone, which was nearly completed as an underground mine, with gold production beginning the first quarter of 2001. Barrick Gold Corp. completed an asset swap with Newmont in May 1999 that provided access to the Deep Post underground deposit zone through a decline at the bottom of the Betze-Post Pit. The asset swap also provided the opportunity to begin a mile-long exploration drift from the Deep Star Mine to the Deep Post Deposit, called the Gold Margin Corridor. Carlin operation's largest open pit mine, Gold Quarry, was mined out in the spring of 2000. In August 2000, mining also ended at the Rosebud underground mine. Exploration drilling near existing gold mines have located an additional 75,000 kg (2.4 million ounces) of gold reserves (Newmont Gold Co., 2001, p. 7).

Barrick Gold Corp. was the Nation's second largest gold mining company in 2000 and reportedly recovered 51,200 kg (1.6 million ounces) of gold at its Betze-Post Mine/Goldstrike in Eureka County. In nearby Elko County, Barrick continued the development of its Meikle Mine/Goldstrike, an underground operation that produced 25,100 kg (806,000 ounces) of gold; it was the Nation's largest underground gold mine. The mine had an underground cooling system to keep temperatures around 80 F even though the temperature of the surrounding rock can be 140 F (Gold News, 1998). These Barrick operations on the Carlin Trend were developed within a 2,800-hectare landholding known as the Goldstrike Property (Barrick Gold Corp., 2001, p. 5).

Northwest of Elko, AngloGold Ltd. and Meridian Gold Inc. produced about 10,700 kg (344,000 ounces) of gold at their Jerritt Canyon Mine, the Nation's 10th largest gold mine (AngloGold Ltd., 2001, p. 20). Other gold mines in Humboldt County included the Hycroft (formerly the Crowfoot/Lewis) and the Marigold Mines.

South of and parallel to the Carlin Trend, the Battle Mountain/Eureka Trend runs from southeastern Humboldt County southeast through Lander and Eureka Counties. Gold mining operations along this trend in Lander County include the Battle Mountain Complex, which was placed on care and maintenance on January 1, 2000 (Battle Mountain Gold Co., 2000, p. 7); the McCoy/Cove gold and silver mine, which produced 5,100 kg (163,000 ounces) (Echo Bay Mines Ltd., 2001, p. 9); and the country's fourth largest gold mine, the Cortez Mine, owned by Placer Dome (60%) and Kennecott Minerals Co. (40%), which produced 31,400 kg (1.0 million ounces) (Placer Dome Inc., 2001, p. 9).

At Round Mountain, about 95 kilometers (km) north of Tonopah, the Round Mountain Gold Corp. mine of Echo Bay Mines Ltd. produced about 19,800 kg (638,000 ounces) of gold during the year (Echo Bay Mines Ltd., 2001, p. 9). The property is the sixth largest U.S. gold mine.

Battle Mountain Gold Co. continued its exploration project by extending the Phoenix Zone at the Battle Mountain Complex, thereby adding about 31,000 kg (1 million ounces) of gold to its reserve base. In addition, Dynatec Corp. continued to develop the Rossi-Storm Deposit at the Ken Snyder Mine, which poured its first gold on December 9, 1998. Ken Snyder's second full year of commercial production was 5,300 kg (171,000 ounces) of gold making it the country's 13th largest gold mine in 2000 (Franco-Nevada Mining Corp. Ltd., 2001, p. 2).

Exploration continued to decline. Activity was concentrated along the major "trends," Battle Mountain, Carlin, Getchell, and Midas. Several companies pursued high-grade vein targets, such as feeder-vein systems beneath the former Hog Ranch open pit mine in Washoe County and the Hollister open pit mine in Elko County (Tingley and LaPointe, 2001, p. 82).

South Dakota.—Gold production decreased by more than 17% compared with that of 1999. Homestake Mining Co's 124-year-old Homestake Mine at Lead will be shut down by the end of 2001. Homestake plans to produce about 7,500 kg (240,000 ounces) of additional gold before closure, and expects to spend over $66 million over 8 years on final reclamation and remediation (American Metal Market, 2000g). The Homestake Mine was again the largest gold-producing mine in South Dakota and the 14th largest gold-producing mine in the country. During the year, the mine, a nearly 2.5-km-deep operation with associated surface mining, yielded about 5,300 kg (171,000 ounces) of gold (Homestake Mining Co., 2001, p. 4).

Goldcorp Inc. operated an open pit gold mine near Lead, the Wharf Mine, which produced about 2,900 kg (94,000 ounces) of gold (Goldcorp Inc., 2001, p. 5).

Utah.—Rio Tinto Ltd.'s Bingham Canyon Mine, which was operated by Kennecott Utah Copper Corp., produced about 16,500 kg (529,000 ounces) of gold as a byproduct of its copper mining operations near Salt Lake City. Long ranked as one of the Nation's principal gold-producing mines, Bingham Canyon was the seventh largest gold producer in 2000. Kennecott also operated the nearby Barney's Canyon Mine, an open pit and heap-leaching operation that produced 4,800 kg (153,000 ounces) of gold (Rio Tinto Ltd., 2001, p. 3).

Digitized by Google

Washington.—Echo Bay Mines's Kettle River underground mine, in the northeastern part of the State, produced 2,900 kg (94,000 ounces) of gold in its 10th year of production (Echo Bay Mines Ltd., 2001, p. 9).

The Crown Jewel project, with projected annual production of 5,400 kg (175,000 ounces) of gold, received an unfavorable ruling on a water-quality permit. The ruling, made by Washington State's Pollution Control Hearings Board, delayed the project's startup date (American Metal Market, 2000d).

World Review

World gold mine production was about the same as in 1999. Increased production from mines in Russia and the United States was enough to help offset a continuing decline in gold output from South Africa. According to its annual review of world gold supply and demand, Gold Fields Mineral Services Ltd. calculated that the total global supply of gold in 2000 was 3.95 Mkg (123 million ounces) compared with the previous year's total supply of 4.15 Mkg (129 million ounces) (Klapwijk and others, 2001, p. 7). Gold Fields Mineral Services also reported level mine production; increases in official sector sales (1.5%); no net producer hedging; and a implied net disinvestment of 291,000 kg (9 million ounces), which was sales of bars and coins by private investors. Old gold scrap levels hardly changed in 2000 (Klapwijk and others, 2001, p. 7).

On the demand side, Gold Fields Mineral Services reported only 5,000 kg (155,000 ounces) less that its 1999 level. Jewelry fabrication increased by 26,000 kg (810,000 ounces) as strong growth in the Middle East outweighed weakness in the Indian subcontinent and Europe. Bar hoarding fell by 18% largely as a result of lower Japanese demand. Coin fabrication collapsed to 46,000 kg (1.4 million ounces), but the amount of gold used in electronics increased by 15% (Klapwijk and others, 2001, p. 10).

With regard to gold exploration, the Metals Economics Group, Halifax, Nova Scotia, Canada, determined from its annual survey of worldwide exploration budgets for 656 companies (diGesu and others, 2000a) that $1.09 billion (46%) of the 2000 world exploration budget total for nonferrous metals was directed to gold, with 428 companies reporting active gold programs. The expenditures for gold were $238 million less than the $1.33 billion (52% of the total) reported for gold exploration in 1999. As in the preceding 6 years, Latin America received the highest expenditure for gold—$662.9 million (28%) of the reported 2000 world total exploration dollars (diGesu and others, 2000b).

Australia.—Australian gold mine production dropped by about 2% from 1999. However, Australia retained its position as the world's third largest gold-producing nation. Of the 296,400 kg (9.2 million ounces) of gold mined in 2000, Western Australia, Queensland, and Northern Territory accounted for about 70%, 12%, and 8%, respectively (Australian Bureau of Agricultural and Resource Economics, 2001, p. 15); Western Australia's production was derived principally from mining operations near Kalgoorlie. Other Australian gold-producing States were, in descending order of output, New South Wales, Victoria, Tasmania, and South Australia.

Cost at the Granny Smith Mine, traditionally one of the lowest producers, doubled. The higher costs were partially a result of lower gold production as waste rock was mined to gain access to an ore zone. In addition, operational difficulties were experienced owing to harsh weather during the first quarter (Klapwijk and others, 2001, p. 45).

The Australian Bureau of Statistics reported that expenditures for mineral exploration in Australia increased during the second quarter of 2000. The 4% increase in spending marked a reversal in the decline of exploration expenditures in Australia since 1997. Spending for gold exploration, which accounted for the largest share of total spending, rose by more than $20 million in the second quarter of 2000 (American Metal Market, 2000a).

Medals for the Sydney Olympics were made from donated newly mined gold and silver, plus old Australian coins that were out of circulation. Each gold metal was made of pure silver with a minimum of 6 grams of gold for plating. During the Olympic Games, 650 gold metals were awarded (American Metal Market, 2000b).

Brazil.—During 2000, gold production declined 1% to about the 52-metric-ton (1.7-million-ounce) level. Output from the informal, noncorporate mining sector, the garimpeiros, was estimated to have dropped to as low as 12,000 kg (370,000 ounces) of gold. Low gold prices, higher fuel prices, stricter environmental controls, and restriction of mining activities in native Indian reserves encouraged garimpeiros to find alternative and more formal employment. Most of the formal mining sector, however, performed well, maintaining about 40,000 kg (1.3 million ounces) of gold production by reducing costs (Klapwijk and others, 2001, p. 37).

Canada.—Canada dropped to fifth position in the ranking of world gold producers, as its output declined by 2% to 154,000 kg. Gold was produced at about 33 lode gold mines, the same as that of 1999. During the year, no gold mines began operation, six gold mines reopened, and six gold mines shutdown or suspended operations. Canada's principal gold-producing Provinces were Ontario (47%), Quebec (22%), British Columbia (17%), and Manitoba (5%). Gold was also produced in Alberta, New Brunswick, Newfoundland, Nunavut, Saskatchewan, the Northwest Territories, and Yukon Territory. The reopening of the Red Lake Mine in northwestern Ontario in August, after 4 years of shutdown due to a labor dispute, was the highlight of the year for gold mining in Canada. Highly successful exploration work, which resulted in the discovery of the nonrefractory High Grade Zone, allowed the mine to be redeveloped into an exceptionally high-grade and low-cost gold mine. The mine is currently the lowest cost gold mine in Canada (Michel Miron, Natural Resources Canada, written commun., 2001).

Chile.—Gold output in Chile increased 19% to 54,000 kg (1.7 million ounces) despite a number of mine closures. Closures included the high-cost Andacollo Mine, which suspended operations in September, and the El Tambo Mine where operations ceased in June due to ore depletion. The new El Peñon had a strong performance, adding just under 10,000 kg (3.0 million ounces) to Chile's gold output in 2000 (Klapwijk and others, 2001, p. 37).

China.—The Chinese produced 180,000 kg of gold in 2000, up 4% from the 173,000 kg of gold produced in 1999 (Platts Metals Week, 2001).

The Chinese Government released an outline of how China is restructuring its gold market in a series of economic reforms to comply with standards set by the World Trade Organization for membership. China is also expected to establish a national gold

Digitized by Google

exchange in 2001, which will trade only spot gold. China produces 180,000 kg of gold from 1,200 mines, and its central bank holds 395,000 kg of gold (American Metal Market, 2000c).

India.—The Delhi Stock Exchange offered online trading in gold bullion early in November and thereby initiated the first stock exchange in India for bullion trading. Almost 29 Mkg of gold, valued at $300 billion, are held in India. The Government holds only about 400,000 kg of gold, with the remainder in private hands. In addition, India imports over 800,000 kg of gold annually to satisfy its demand for jewelry (American Metal Market, 2000e).

Indonesia.—Gold output was estimated to have dropped by 2% in 2000 to 125,000 kg. The Grasberg Mine, which produced 96,000 kg of gold, generated as a byproduct 77% of the country's gold output. Also, the Minahasa and Kelian Mines declined in gold output owing to industrial action and community protests through road blocks. Losses were more than offset by extra gold output from two new gold mining operations: The Gosowong Mine produced more than 7,000 kg of gold in its first full year of operation. In addition, the Batu Hijau copper-gold mine shipped its first concentrate at the end of 1999 and contributed almost 10,000 kg to Indonesian gold output in 2000 (Klapwijk and others, 2001, p. 39).

Mexico.—Gold production increased by 11% to almost 26,000 kg in 2000 (Klapwijk and others, 2001, p. 37).

The International Monetary Fund (IMF) has completed its planned sales of over 400,000 kg (13 million ounces) of gold by reevaluating the gold without depressing the gold market. Seven off-market transactions were made with the borrowing countries, Brazil and Mexico, selling the gold, buying it back, and raising cash by reevaluating the gold. The off-market transactions were part of an agreement to fund the IMF's share of the "Highly Indebted Poor Countries" (HIPC) initiative. IMF sold its gold to Brazil and Mexico and accepted it back immediately from Brazil and Mexico for payment of an obligation due that same day. IMF takes advantage of the difference between the value of gold on its books and the much higher market price. The cash is then invested and the interest is used to support the HIPC initiative (American Metal Market, 2000f).

Papua New Guinea.—Gold production in Papua New Guinea rose over 21% to 74,000 kg. Porgera Mine showed a 20% increase in gold production owing to higher grades and improved recovery at the plant. Record gold output of 16,000 kg was reported at the Ok Tedi Mine, however, it is still embroiled in a protracted court battle with landowners over damage caused by waste in rivers around the mine (Klapwijk and others, 2001, p. 40).

Peru.—For the fifth consecutive year, gold production in Peru exceeded that in Brazil, making it the largest gold producer in Latin America at 133,000 kg of gold, which was 3% more than that of 1999. Gains at the Yanacocha and Orcopampa Mines were enough to offset the losses from the Pierina Mine where gold output declined 2%, as lower grade ore was processed. Further losses of 25% were expected and reported at the Sipan Mine. Production is expected to rise even further at the large-scale, low-cost, open pit, heap-leach Yanacocha Mine in northern Peru, when La Quinua (one of the five deposits that constitute the Yanacocha Mine) is brought into production in 2001 (Klapwijk and others, 2001, p. 36).

Russia.—Production in Russia grew by 11%, to 140,000 kg of gold, moving Russia to the sixth position among the top gold producing countries. Two years of strong growth in gold production indicate that gold reserves are available to be mined should Russian owners receive adequate financial backing. Liberalization in the gold industry, which started a few years ago and accelerated after the economic crisis of 1998, allowed many commercial banks to obtain licenses for trading and exporting gold. The proliferation of these banks has provided more than sufficient funding to the gold industry, which buys between 70% and 80% of the gold from the mines. Much of the buying is completed through prepurchasing schemes entered into before the gold is produced. Most of the gold is exported with a 5% export duty on precious metals ores and concentrate imposed by the Central Bank (Klapwijk and others, 2001, p. 40).

South Africa.—Gold production in South Africa, the world's largest gold-producing nation, declined for the seventh consecutive year, to 431,000 kg of gold, 5% less than that of 1999, and left gold production at its lowest level in 46 years. South Africa has not had a year-on-year increase in gold output since 1993, and consequently with the increase in gold production in Australia and North America, its share fell from 30% of the world's gold output in 1993, to roughly 17% in 2000. The successive declines can, in part, be explained by operational difficulties related to the maturity of the industry and the nature of the ore deposits: narrow veins in hard rock being mined at deep levels. In 2000, the number of working shifts were reduced, which also affected gold production (Klapwijk and others, 2001, p. 33).

The tonnage and grade of ore milled during 2000 by the mines comprising the membership of the Chamber of Mines of South Africa amounted to almost 84 billion kilograms at a grade of 4.51 grams per ton of gold ore; this compares with a higher total tonnage of 87 billion kilograms at a higher grade of 4.62 grams per ton that was milled by Chamber members in 1999.

Of the top 15 gold-producing companies in the world in 2000, 4 were South African. AngloGold Ltd., listed on the Australian Stock Exchange in November 1999, remained the leading gold-producing company in the world. Gold Fields Ltd. was third in the world. The other two companies were Harmony Gold Mining Co. Ltd. (8th) and Durban Roodepoort Deep Ltd. (12th). Durban Roodepoort Deep was listed on the Australian Stock Exchange in March 1999 (Klapwijk and others, 2001, p. 31).

Uzbekistan.—Gold production in Uzbekistan remained constant at 85,000 kg. Gold output at the Zarafshan-Newmont Gold's joint venture, which processes high-grade tailings from the state-owned Muruntau Mine at Zarafshan, dropped by 8% primarily due to changes in production levels. In addition, Navoi Mining and Minerals, operators of the Muruntau Mine in the Kyzylkum desert, reported throughput and fine gold recovery increased. Navoi announced plans to start building a biooxidation plant at its Uchkuduk site, which could see gold output increase further in the future (Klapwijk and others, 2001, p. 41).

Outlook

World gold producers are expected to reduce capital spending during the next 2 or 3 years. Small-to-medium-sized companies will be absorbed by the larger gold mining companies, and the

Digitized by Google

largest companies will merge as a consolidation phase takes place in the gold mining industry. This trend of consolidation to maintain gold reserves is expected to continue; thus, forecasts of a future gold industry comprised of less than 10 major companies cannot be easily dismissed. Moreover, larger companies that produce as much as 300,000 kilograms per year of gold could materialize in the next 2 to 3 years.

Capital spending reductions will occur; this means less gold exploration and suggests that new pipeline projects will not be sufficient to replace old ones. The U.S. gold industry already has been closing its gold mines, 10 in 1999 and 12 more in 2000. It is not only the low price of gold that drives spending down; it is also due to lack of investor interest because too many gold companies are generating poor returns.

TABLE 1
SALIENT GOLD STATISTICS 1/

		1996	1997	1998	1999	2000
United States:						
Mine production	kilograms	326,000	362,000	366,000	341,000	353,000
Value	thousands	$4,090,000	$3,870,000	$3,480,000	$3,070,000	$3,180,000
Gold recovered by cyanidation:						
Extracted in vats, tanks, closed containers 2/	kilograms	170,000	201,000	238,000	196,000	90,000
Leached in open heaps or dumps 3/	do.	124,000	132,000	103,000	131,000	193,000
Refinery production:						
Concentrates and doré	do.	NA	270,000	277,000	265,000	197,000
Recycled materials (new and old scrap)	do.	NA	100,000	163,000	143,000	81,600
Exports, refined	do.	406,000	391,000	430,000	435,000	440,000
Imports for consumption, refined	do.	143,000	194,000	257,000	196,000	184,000
Net deliveries from foreign stocks in Federal Reserve Bank of New York	do.	373,000	143,000	310,000	303,000 r/	356,000
Stocks, December 31:						
Industry 4/	do.	NA	17,300	16,600	14,700	9,300
Commodity Exchange (Comex) 5/	do.	20,700	15,200	25,200	37,900	52,900
Department of the Treasury	metric tons	8,140	8,140	8,130	8,170	8,140
Volume of U.S. Gold Futures Trading 6/	do.	14,300	29,700	28,600	29,800	20,600
Department of the Treasury: 7/						
American Eagle gold coin	kilograms	10,700	20,000	49,200	78,200	13,900
Other numismatic gold coins	do.	1,190	500	86	430	330
Consumption in industry and the arts	do.	NA	137,000	219,000	245,000	183,000
Apparent demand, refined 8/	do.	NA	265,000	667,000	283,000	380,000
Price, average per troy ounce 9/		389	332	295	280	280
Employment, mine and mill only 10/		16,900	16,300	13,400	10,300	10,400
World:						
Production, mine	kilograms	2,290,000 r/	2,450,000	2,510,000 r/	2,550,000 r/	2,550,000 e/
Official bullion reserves 11/	metric tons	34,400	34,000	33,600	33,500 r/	33,000

e/ Estimated. r/ Revised. NA Not available.

1/ Data are rounded to no more than three significant digits, except prices.

2/ May include small quantities recovered by gravity methods.

3/ May include tailings, waste-ore dumps, and previously mined ore at some inactive mines.

4/ Unfabricated refined gold held by refiners, fabricators, dealers, and the U.S. Department of Defense.

5/ Commodity Exchange (Comex) Division of the New York Mercantile Exchange.

6/ Comex only.

7/ Fiscal year bullion disbursements to U.S. Mint coin programs. Fiscal year begins October 1, of year prior to year indicated.

8/ Defined as refinery production from primary materials plus refinery production from old scrap plus net bullion flow to market from foreign stocks at the New York Federal Reserve Bank plus net imports of bullion. Assumed to include gold held for investment purposes. Excludes gold contained in fabricated items, imported coins, and official monetary gold.

9/ Engelhard Corp. industries quotation.

10/ Data from Mine Safety and Health Administration.

11/ Held by central banks, governments, and international monetary organizations. Data from International Monetary Fund.

TABLE 2
MINE PRODUCTION OF GOLD IN THE UNITED STATES, BY STATE 1/

(Kilograms)

State	1999	2000
Alaska 2/	16,200 r/	15,600
Arizona	786	442
California	17,500	17,200
Idaho	W	W
Montana	7,540 r/	9,310
Nevada	256,000 r/	268,000
South Dakota	10,300 r/	8,230
Washington	3,250	2,930
Other States 3/	29,700 r/	31,700
Total	341,000	353,000

r/ Revised. W Withheld to avoid disclosing company proprietary data, included with "Other States."
1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Production data collected by the State.
3/ Includes Colorado, New Mexico, South Carolina, Utah, Wisconsin, and States indicated by symbol W.

TABLE 3
LEADING GOLD-PRODUCING MINES IN THE UNITED STATES IN 2000, IN ORDER OF OUTPUT 1/

Rank	Mine	County and State	Operator	Kilograms
1	Betze-Post/Goldstrike	Eureka, NV	Barrick Gold Corp.	51,200
2	Twin Creeks 2/	Humboldt, NV	Newmont Gold Co.	41,100
3	Carlin operations 2/	Elko, Eureka, NV	do.	37,000
4	Cortez	Lander, NV	Placer Dome Inc.	31,400
5	Meikle/Goldstrike 3/	Elko, NV	Barrick Gold Corp.	25,100
6	Round Mountain	Nye, NV	Round Mountain Gold Corp.	19,800
7	Bingham Canyon 4/	Salt Lake, UT	Kennecott Utah Copper Corp.	16,500
8	Lone Tree 2/	Humboldt, NV	Newmont Gold Company	15,100
9	Fort Knox 5/	Fairbanks, AK	Fairbanks Gold Mining Inc.	11,300
10	Jerritt Canyon	Elko, NV	Independence Mining Co., Inc.	10,700
11	Cresson	Teller, CO	Cripple Creek & Victor Gold Mining Co.	7,700
12	Golden Sunlight	Jefferson, MT	Placer Dome Inc.	6,600
13	Ken Snyder	Elko, NV	Euro-Nevada Mining Co.	6,040
14	Homestake	Lawrence, SD	Homestake Mining Co.	5,320
15	McCoy/Cove	Lander, NV	Echo Bay Mines Ltd.	5,060
16	Barney's Canyon	Salt Lake, UT	Kennecott Barney's Canyon Mining Co.	4,760
17	Bald Mountain	White Pine, NV	Placer Dome Inc.	4,180
18	Mesquite 2/	Imperial, CA	Newmont Gold Co.	4,060
19	Ruby Hill	Eureka, NV	Homestake Mining Co.	3,890
20	Castle Mountain	San Bernardino, CA	Viceroy Resources Corp.	3,690
21	McLaughlin	Napa, Yolo, CA	Homestake Mining Co.	3,350
22	Denton-Rawhide	Mineral, NV	Kennecott Rawhide Mining Co.	3,250
23	Rand	Kern, CA	Glamis Rand Mining Co.	3,110
24	Kettle River	Ferry, WA	Echo Bay Mines Ltd.	2,930
25	Wharf	Lawrence, SD	Wharf Resources, Ltd.	2,920
26	Briggs	Inyo, CA	Canyon Resources Corp.	2,690
27	Greens Creek 6/	Juneau, AK	Kennecott Greens Creek Mining Co.	2,510
28	Rochester	Pershing, NV	Coeur d'Alene Mines Corp.	2,360
29	Beartrack	Lemhi, ID	Meridian Gold Inc.	2,250
(7/)	Florida Canyon	Pershing, NV	Florida Canyon Mining, Inc.	W

W Withheld to avoid disclosing company proprietary data.
1/ Data are rounded to no more than three significant digits; these mines accounted for more than 96% of the U.S. gold production in 2000.
2/ Mill output.
3/ Previously reported county location was incorrect.
4/ Mine production refers to total quantity of gold produced in concentrates.
5/ Mine production refers to gold equivalent produced.
6/ Updated to reflect locality name change.
7/ Production at Florida Canyon is withheld; mine is among the top 30 gold-producing mines in the United States, but is not shown in rank order to avoid disclosing company propriety data.

e/ Estimated. p/ Preliminary. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Table includes data available through August 11, 2000.

3/ Reported figure.

4/ Officially reported figures are as follows, in kilograms: Major companies: 1996--41,142; 1997--41,062; 1998--41,000 (estimated); and 1999-2000-not available. Garimpos 1995--23,473; 1996--18,869; 1997--17,426; 1998--17,500 (estimated); and 1999-2000--not available.

5/ Includes undocumented artisanal production.

6/ Year ending July 7 of that stated.

7/ Undocumented artisanal production.

8/ Refinery output.

9/ Excludes production from so-called people's mines, which may be as much as 18,000 kilograms per year, but includes gold recovered as byproduct of copper mining.

10/ Includes documented production from placer artisanal production.

11/ Data are based on official exports and do not reflect gold moved through undocumented channels.

12/ Government estimates unreported production as high as 30,000 kilograms.

13/ Indicates byproduct of base metals.

14/ Year beginning April 1 of that stated. Byproduct of copper production by Zambia Consolidated Copper Mines Ltd. only. Some additional artisan production was reported, but data are insufficient to make reliable estimates.

GRAPHITE

By Rustu S. Kalyoncu

Domestic survey data and tables were prepared by Joseph M. Krisanda, statistical assistant, and the world production table was prepared by Glenn J. Wallace, international data coordinator.

Graphite is one of three forms of crystalline carbon; the other two are diamond and fullerenes. Graphite occurs naturally in metamorphic rocks such as marble, schist, and gneiss. It is a soft mineral, also known by the names of black lead, plumbago, and mineral carbon. The word graphite is derived from the Greek word "graphein," to write. It has a Mohs hardness of 1 to 2 and exhibits perfect basal cleavage. Depending upon the purity, the specific gravity is 2.20 to 2.30. The theoretical density is 2.26 grams per cubic centimeter. It is gray to black in color, opaque, and has a metallic luster. It is flexible but not elastic. It has high thermal and electrical conductivities, is highly refractory, and is chemically inert.

Two general types of graphite, natural and synthetic, are encountered. Worldwide, natural graphite deposits occur as lenses or layers of disseminated or massive flakes. Graphitization of naturally occurring organic carbon may occur at temperatures as low as 300° C to 500° C or as high as 800° C to 1,200° C, such as when an igneous intrusion contacts a carbonaceous body.

The three principal types of natural graphite—lump, crystalline flake, and amorphous—are distinguished by physical characteristics that are the result of major differences in geologic origin and occurrence. Lump graphite occurs in veins and is believed to be hydrothermal in origin. It is typically massive, ranging in particle size from extremely fine to coarse, platy intergrowths of fibrous or acicular crystalline aggregates with the long axis parallel to the enclosing wall rock (Kenan, 1984). Crystalline flake graphite consists of isolated, flat, plate-like particles with angular, rounded, or irregular edges. It is usually found in layers or pockets in metamorphic rocks. In some deposits, the flake graphite occurs as massive accumulations in veins, lenses, or pods. Amorphous graphite is formed by the thermal metamorphism of coal. The designation amorphous is a misnomer. Its relatively low degree of crystalline order and very fine particle size make it appear amorphous. It is usually of lower purity than the crystalline flake graphite and, therefore, commands a lower price than its more ordered counterpart.

Beneficiation processes for graphite may vary from a complex four-stage flotation at the European and U.S. mills to simple hand sorting and screening of high-grade ore at the Sri Lanka operations. Certain soft graphite ores, such as those found in Madagascar, need no primary crushing and grinding. Typically, such ores contain the highest proportion of coarse flakes. Ore is sluiced to the field washing plant where it undergoes desliming to remove clay fractions and is subjected to a rough flotation to produce a concentrate with 60% to 70% carbon. This concentrate is transported to the refining mill for further grinding and flotation to reach 85% carbon and screened to a variety of products marketed as flake graphite containing 75% to 90% carbon.

Legislation and Government Programs

Total national defense stockpile graphite inventories, including nonstockpile-grade, were 8,730 metric tons (t) with a value of about $1.65 million. Madagascar natural graphite inventories in the United States were 3,870 t with a value of

Graphite in the 20th Century

In 1900, 555 metric tons of graphite valued at $198,000 was produced in the United States. Michigan, New York, Pennsylvania, Rhode Island, and Wisconsin were the only graphite producing States in 1900. In contrast to production, 14,000 tons of graphite valued at $1.4 million were imported. Imports were mostly from Ceylon. In the early 1900s, natural graphite found uses in the manufacture of lead pencils, lubricants, and few electrical applications. Such uses continued throughout the mid-1950s.

There has been no graphite mined in the United States since 1990, when United Minerals Co. suspended its graphite mining operations at its Montana mine, but 60,800 tons of natural graphite was imported, mainly, in decreasing order, from China, Canada, Brazil, Mexico, and Madagascar. In 2000, the United States produced 290,000 tons of synthetic graphite valued at $771 million, and exported 94,000 tons of graphite products at a value of $97 million. Today, with the development of techniques to synthesize graphite from organic materials and advanced purification methods for natural graphite, there are myriad applications for both natural and synthetic graphite. Natural graphite of 99.8% purity can compete with synthetic graphite in a number of applications such as fiber composites. Developments in the area of materials engineering and the ability to process fibers and synthesize graphite from organic precursors have made graphite truly a high technology material that has uses such as high-strength graphite fiber composites for space age applications. The next important development in the use of graphite will come in the energy field: advanced automotive batteries and fuel cells. Fuel cells alone, once fully developed and marketed, will account for more than half the graphite consumption in the United States.

Digitized by Google

$600,000. There were 4,810 t of Sri Lanka amorphous lump with a value of $1.10 million (table 2). No acquisition of graphite for the strategic and critical materials stockpile occurred in 2000. Graphite no longer has a Government stockpile goal and all graphite in the Government stockpile has been authorized for sale.

Production

No graphite was mined in the United States in 2000. The reported U.S. production of synthetic graphite reached 290,000 t with a value of $771 million (table 4).

Graphite is mined from open pit and underground mine operations. Open pit operations are more economical and, thus, are preferred where the overburden can be removed economically. Mines in Madagascar are mostly of this type. In the Republic of Korea, Mexico, and Sri Lanka, where the deposits are deep, underground mining techniques are required.

Consumption

The use of graphite has changed dramatically. Graphite exhibits the properties of a metal and a nonmetal, which makes it suitable for many industrial applications. The metallic properties include thermal and electrical conductivity. The nonmetallic properties include inertness, high thermal resistance, and lubricity. The combination of conductivity and high thermal stability allows graphite to be used in many applications such as refractories, batteries, and fuel cells. Lubricity and thermal conductivity make it an excellent material for high-temperature applications, because it results in a material that provides effective lubrication at a friction interface while furnishing a thermally conductive matrix to remove heat from the same interface. Lubricity and electrical conductivity allow its use as the primary material in the manufacture of brushes for electric motors. A graphite brush effectively transfers electric current to a rotating armature while the natural lubricity of the brush minimizes frictional wear. Today's high technology products, such as friction materials and battery and fuel cells, demand higher purity graphite.

U.S. consumption of natural graphite increased by more than 20% in 2000 to 41,800 t from 34,600 t in 1999 (table 3). The crystalline grade increased in 2000 by only 3.5% to 17,900 t from 17,300 t in 1999, whereas amorphous grade increased by an impressive 38% in 2000 to 23,900 t from 17,300 t in 1999. This increased use translated into a more than 50% increase in value in 2000.

The four major industries—refractories, brake linings, lubricants, and foundries—for which natural graphite is used continued their dominance in graphite usage, accounting for one-half of the graphite consumed by U.S. industry in 2000 (table 3). The refractories industry was again the major consumer of crystalline flake graphite followed by the manufacture of brake linings and metal powders. Refractory applications of graphite included castable ramming, gunning mixtures, and carbon-bonded brick. Carbon-magnesite brick has applications in high-temperature corrosive environments such as steel furnaces, ladles, and iron blast furnaces. Carbon-alumina linings are principally used in continuous steel-casting operations. Magnesite- and alumina-carbon brick requires a particle size of 100 mesh and a purity of 95% to 99% graphite.

Crystalline flake graphite accounted for nearly 45% of graphite usage in the United States. It was used mainly in refractories, batteries, and other thermal and electrical conductivity applications. Amorphous graphite is mainly used as a lubricant additive, as a pigment in paints; in plastic refractories, and in other applications where additions of graphite improve the process or the end product. Lump graphite finds appropriate uses in a number of areas, such as steelmaking, depending on the purity and particle size.

Synthetic graphites remain the choice in North America, accounting more than half of the market. The main market for high purity synthetic graphites is iron and steel as a carbon-raiser additive. This market consumes more than 50% of the synthetic graphite.

Other significant uses of all types of graphites are in the manufacture of low-current, long-life batteries, steelmaking, solid carbon shapes, static and dynamic seals, valve and stem packing, catalyst supports, porosity enhancing inert fillers, manufacture of rubber, and powder metallurgy. The use of graphite in low-current batteries is gradually giving way to carbon black, which is more economical.

Prices

Graphite prices remained unchanged during 2000. Prices for crystalline flake graphite concentrates ranged from $480 to $550 per metric ton and commanded higher prices than the amorphous, which was priced at $220 to $235 per ton (table 5). Carbon content, flake and crystal size, size distribution, and ash content affect the price of graphite. The price of synthetic graphite, however, declined to $1.94 per kilogram in 2000 from $2.29 per kilogram in 1999. Customary negotiations between the buyer and the seller lead to wide price fluctuations.

Foreign Trade

Total imports of natural graphite increased in tonnage to 60,800 t in 2000 from 55,800 t in 1999, but the value declined to $32.5 million in 2000 compared with $34.7 million in 1999 (table 7). Principal import sources of natural graphite were China, Canada, Mexico, Japan, Madagascar, and Brazil, in order of tonnages, which accounted for 89% of the value of total imports. Mexico continued to be the major supplier of amorphous graphite and Sri Lanka provided the lump variety. A number of other producers supplied various types and grades of graphite to the United States, among the more notable being Japan and Germany.

In spite of showing a noticeable decrease in tonnage, total exports recorded an impressive 16% increase in total revenue to $96.5 million in 2000 compared with $82.8 million in 1999 because of the increase in value of the finished goods exported (table 6).

World Review

World production of graphite in 2000 was estimated to be 602,000 t compared with 600,000 t in 1999. China maintained

Digitized by Google

its position as the world's leading graphite producer with 220,000 t, with India in second place with 140,000 t, followed by Brazil, Mexico, and the Czech Republic, in order of importance. These five countries accounted for over three-quarters of the world production (table 9).

Sri Lanka continued to account for nearly all the high-purity lump graphite produced. Sri Lankan deposits were estimated to average 95% graphite in situ. China accounted for 37% of world production.

Current Research and Technology

In recent years, new technology in processing and treatment has expanded the use of natural graphites in battery applications. Graphite for these applications is purified to 99.9% carbon. Most new uses for graphite products are being developed through advances in graphite thermal technology. The ability to refine and modify graphite and carbon products will be the key to future growth in the graphite industry. Innovative refining techniques have enabled the use of improved graphite in friction materials, electronics, foil, and lubrication applications (Hand, 1997). Some of the new application areas include electrically conductive asphalt for heated runways at airports and roadway bridges.

With its low specific gravity, refractoriness, and corrosion resistance, graphite is critical for many industrial applications, such as dies for continuous casting, rocket nozzles, and heat exchangers for the chemical industry. Relatively poor wear and oxidation resistance of graphite, however, limit its use. A class of high-performance materials based on titanium carbide-coated graphite makes the material suitable for some of the most demanding applications (Webb, 2000). Because titanium carbide is one of the hardest and most durable materials, the resulting components are extremely resistant to wear, corrosion, and elevated temperatures. These composites can be engineered to fit many industrial uses through control of the coating composition, thickness, microstructure, and surface finish. In metal melting applications titanium carbide coatings have been shown to improve the service life of the graphite components by as much as fivefold.

Advanced refining technology in the next few years, despite a weak refractory market and pricing pressure from Chinese material, could bring a reversal of fortune to the graphite industry.

Enigmatic clusters of carbon atoms, called fullerenes, which are found as large carbon-cage molecules, have been puzzling scientists since 1985 when they were first discovered among the byproducts of laser-vaporized graphite (Pierson, 1993). Their hollow spherical structure, reminiscent of geodesic domes of architect Buckminster Fuller, earned them the names "buckyballs" and "fullerenes." Mistakenly called a new form of carbon, fullerenes have been found to exist in interstellar dust as well as in geological formations on Earth. Fullerenes are fascinating because they exhibit unusual properties for carbon materials. For example, adding 3 alkali atoms per fullerene unit (C_{60}) results in a material that exhibits superconductivity at quite high temperatures (10° K to 40° K). These materials also exhibit lubricity superior to that of graphite. To date, no product based on fullerenes has been offered in the market. The full potential of fullerenes in practical applications remains to be explored.

Outlook

The main areas of natural graphite consumption in the near future will be in high temperature applications for the iron and steel industry as the industry modernizes its production facilities. Brake linings and other friction materials will steadily consume more natural graphite as new automobile production continues to increase and more replacement parts are required for the growing number of vehicles. Flexible graphite product lines, such as grafoil (a thin graphite cloth), will probably be the fastest growing market but will consume small amounts of natural graphite compared with major end-use markets.

The advent of hybrid and electric vehicles is expected to bring increased demand for high-purity graphite in fuel cell and battery applications. One optimistic prediction is that the demand for high quality, high carbon graphite could increase to more than 100,000 metric tons per year (t/yr) for fuel cell and battery applications alone (Crossley, 2000). The global demand for graphite used in batteries may double to more than 25,000 t/yr in the next 5 years. This demand is expected to be spread between the two main consuming sectors-alkaline batteries and lithium-ion batteries. Synthetic and natural graphite are both used in these batteries.

In alkaline batteries, graphite is the conductive material in the cathode. Until recently, synthetic graphite was dominantly used in these batteries. But with the advent of new purification techniques and more efficient processing methods, it has become possible to improve the conductivity of most natural graphite to the point where it can be used in batteries. The decision whether to use synthetic or natural graphite will be a balancing act between price and performance. The growth of the lithium-ion battery market could have a more dramatic effect on the graphite market as the demand rises for mobile energy storage systems.

Fuel cells convert hydrogen into electricity by an electrochemical reaction. The hydrogen molecules break down into protons and electrons at the cell's anode. Protons are then conducted through the electrode and the electrons travel through an external circuit and generate electricity. Graphite, as cathode material, forms a crucial part of fuel cell technology. Some predictions show that consumption of graphite in fuel cell electrodes could reach 80,000 t/yr in just 2 to 3 years. Canada, Germany, Japan, and the United States are aggressively promoting fuel cell development. The cost of fuel cells, however, is still too high for commercial vehicles. The price per unit needs to drop to about $1,500 before they will be viable. Daimler-Chrysler Corporation has pledged to have a commercially viable fuel cell vehicle by 2004, and trials for fuel cell buses, taxis, and bicycles have already begun.

In the event of any price increases, China may increase its production to take advantage of potentially increased profits, leading to a sharp price decline in certain grades and possibly to a production stoppage in other countries. If the Chinese iron and steel industry, however, expands its consumption of natural graphite, Chinese exports may eventually decline, encouraging new producers to enter the market (Roskill Information

Digitized by Google

Services Ltd., 1998).

Industry trends that appear to be common to advances in graphite technology and markets include higher purity and consistency in specifications for some specialized and high-tech applications. Production of higher purity graphite using thermal processing and acid leaching techniques continues to be the trend. This material has applications as advanced carbon-graphite composites.

GYPSUM

By Donald W. Olson

Domestic survey data and tables were prepared by Virginia C. Harper, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Gypsum is one of the most widely used minerals in the world. In the United States, most gypsum is used to manufacture wallboard for homes, offices, and commercial buildings. An average new American home contains more than 7.31 metric tons (t) of gypsum or, in other terms, more than 6,144 square feet (571 square meters) of gypsum wallboard (Mineral Information Institute, 2001). Worldwide, gypsum is used in portland cement, which is used in concrete for highways, bridges, buildings, and many other structures that are part of our everyday life. Gypsum is also extensively used as a soil conditioner on large tracts of land in suburban areas and in agricultural regions.

After a record setting year in 1999, the gypsum industry in the United States experienced a decline in both production and consumption in 2000. In addition, crude gypsum and wallboard imports declined in 2000. Synthetic gypsum generated by various industrial processes continued to increase as a raw material source for wallboard plants.

During 2000, the U.S. gypsum industry experienced several acquisitions and announcements of construction of new plants and of expansion of production capacity at existing plants. Also in 2000, several older, less efficient manufacturing facilities were closed. In October, U.S. Gypsum Co. closed its old plant in Plaster City, CA, and in December, it closed plants in Gypsum, OH, and Plasterco, VA. In June, U.S. Gypsum opened a plant in Aliquippa, PA; in August, it opened a new plant in Plaster City, CA; and in December, it opened a plant in Rainier, OR. Of these three new plants, the Aliquippa uses synthetic gypsum as its raw material, the Plaster City uses natural gypsum brought in by rail from a nearby quarry, and the Rainier is supplied by natural gypsum imported from Mexico. These openings and closings resulted in a net increase in wallboard production capacity of 1.40 billion square feet (130 million square meters). Georgia-Pacific Corp. closed two of its Grand Rapid, MI, wallboard plants—one in January and the other in November. James Hardie Gypsum acquired the gypsum mining claims of Western Gypsum near St. George, UT, during 2000; this gypsum will supply the Blue Diamond plant at Las Vegas, NV. James Hardie Gypsum also announced plans to build three new joint treatment manufacturing plants; the first of the three started operations in the last quarter of 2000 in Kent, WA. National Gypsum Co. began building the Apollo Beach wallboard plant near Tampa, FL. The plant began operating during the first quarter of 2001; it will have production capacity of 600 million square feet per year (55.8 million square meters per year). This plant supplemented the existing wallboard plant in the Tampa area; both Tampa area plants use synthetic gypsum as their raw material. During the last quarter of 2000, American Gypsum Co. (a subsidiary of Centex Construction Products, Inc.) purchased Republic Gypsum Co. and its wallboard plant in Duke, OK. Lafarge Gypsum completed a new Silver Grove, KY, wallboard plant, near Cincinnati, OH. The new plant will use synthetic gypsum as its raw material. Lafarge has built another wallboard plant in Palatka, FL, which was scheduled to come online in early 2001. This plant also will use synthetic gypsum as its raw material. In

Gypsum in the 20th Century

In 1900, U.S. production of gypsum was about 539,000 metric tons valued at approximately $1.63 million. About 85% of this production was in Iowa, Kansas, Michigan, New York, and Texas. In 1900, the United States also imported about 216,000 tons of gypsum valued at $316,000, mostly from Canada. Of the total domestic gypsum production, about 86% was calcined into plaster of paris, 8% was ground for agricultural use, and the remaining 6% was sold as crude and was probably later ground for agricultural use by consumers. A large quantity of plaster of paris was used in the manufacture of wall plasters for office buildings and for the construction of temporary buildings. In the construction industry in 1900, plasters made from gypsum were beginning to displace softer ones made from lime. Gypsum wallboard was first produced in 1916, and by the 1950s and 1960s, plasters were largely displaced by the use of wallboard.

In 2000, domestic crude gypsum output was approximately 19.5 million metric tons and was valued at $165 million. The top producing States, in descending order, were Oklahoma, Iowa, Michigan, Nevada, Texas, California, and New Mexico, which together accounted for 67% of total output. Overall, 30 companies produced gypsum at 56 mines in 19 States, and 10 companies calcined gypsum at 64 plants in 29 States. In 2000, the United Stated also imported about 9.21 million tons of gypsum valued at $89.3 million, mostly from Canada and Mexico. Synthetic gypsum from coal-fired electric powerplants totaling 4.38 million tons made up 15.3% of the total domestic gypsum supply for the year 2000. Most domestic consumption, which totaled approximately 34 million tons, was accounted for by manufacturers of wallboard and plaster products. More than 3.8 million tons for cement production, approximately 1.9 million tons for agricultural applications, and small amounts of high-purity gypsum for a wide range of such industrial processes as smelting and glassmaking accounted for the remaining production.

Digitized by Google

July 2000, British Plasterboard, plc, a London-based firm, acquired the four gypsum wallboard operations of Celotex Corporation located in Cody, WY, Fort Dodge, IA, Jacksonville, FL, and Port Clinton, OH. The new company is called BPB Celotex. BPB Celotex completed a new wallboard plant near Carrollton, KY, with production capacity of 700 million square feet per year (65 million square meters per year). The raw material for the new plant is synthetic gypsum (Sharpe, 2001).

Gypsum industry data for this report are collected by the U.S. Geological Survey (USGS) from semiannual and annual surveys of gypsum operations and are derived from monthly statistics provided by the Gypsum Association in Washington, DC. The 2000 USGS survey, which canvassed 103 gypsum production operations, accounting for almost all domestic output, had a response rate of approximately 93%. The output of producers who did not respond to the survey was estimated from their survey responses in previous years or from other sources familiar with the gypsum industry.

Production

The United States continued to lead the world in gypsum production in 2000, accounting for 18.5% of reported global output. During 2000, domestic output of crude gypsum decreased by 12.8% from that of 1999 to 19.5 million metric tons (Mt) valued at $165 million (table 1).

Crude gypsum was mined in the United States by 30 companies at 56 mines in 19 States. Most of the gypsum, however, was mined by only 4 companies with 25 mines. The top producing States, in descending order, were Oklahoma, Iowa, Michigan, Nevada, Texas, California, New Mexico, Arkansas, Kansas, and Indiana. These States, with 40 mines, each produced more than 1 Mt and together accounted for 84% of total domestic output (table 2).

The U.S. gypsum industry consisted primarily of a few large, vertically integrated companies that mined gypsum and manufactured wallboard, plaster, and other gypsum products. Companies with the most mines were U.S. Gypsum with nine; Georgia-Pacific, seven; National Gypsum, seven; Harrison Gypsum Inc., three; Celotex, two; and James Hardie Gypsum, two. These companies produced almost 71.3% of total U.S. crude gypsum. The 10 largest gypsum mines in the United States accounted for 42.4% of domestic output in 2000. These mines, which were owned by eight companies, had an average output of 829,000 t.

During 2000, gypsum was "calcined" (partially dehydrated by heating) at 64 plants operated by 10 companies in 29 States, principally to produce feedstock for wallboard and plaster plants. The leading States, in descending order, were California, Washington, Texas, Nevada, New York, and Florida. These States, with 24 plants, each produced more than 1.3 Mt of calcined gypsum and together accounted for approximately 43.6% of national output (table 3).

Companies with the most calcining plants were U.S. Gypsum with 21; National Gypsum, 18; Georgia-Pacific, 11; and Celotex, 4. These companies produced 73.7% of national output. The largest 10 calcining plants in the United States accounted for 34.4% of production in 2000. These plants, owned by six companies, had an average output of more than 722,000 metric tons per year.

In addition to mined gypsum production, synthetic gypsum was generated as a byproduct by various industrial processes. The primary source of synthetic gypsum was flue gas desulfurization (FGD) at coal-fired electric powerplants. Smaller amounts of synthetic gypsum were derived from acid neutralization processes. Synthetic gypsum was used as a substitute for mined gypsum, principally for wallboard manufacturing, agricultural purposes, and cement production. In response to USGS surveys, six companies operating in seven States reported that approximately 569,000 t of synthetic gypsum generated by industrial processes at their plants was sold or used for such applications in 2000. In addition to these companies, about 80 domestic coal-fired electric utilities generated approximately 23.3 Mt of synthetic gypsum from their FGD systems during 2000 (American Coal Ash Association, written commun., 2001). Only 4.38 Mt of the synthetic gypsum generated during the year was used, primarily for wallboard production. Use of synthetic gypsum grew by approximately 8.7% during 2000 (Kalyoncu, 2001).

During 2000, 10 companies manufactured gypsum wallboard at 80 plants in the United States. Plant production capacity was expanded by 10.1% to 35.2 billion square feet (3.27 billion square meters) by yearend (Gypsum Association, 2000, 2001). Several new wallboard plants became operational during 2000, providing additional production capacity and replacing older, less efficient manufacturing facilities (Sharpe, 2001). Wallboard shipments during 2000 decreased by 3.18% from those of 1999 to approximately 28.2 billion square feet (2.62 billion square meters). This represents only 80% of the total production capacity (Gypsum Association, 2000, 2001).

Eleven new wallboard plants have been completed or will be completed by yearend 2001. All but one of the new plants will use as their raw material only high-quality, low-cost synthetic gypsum generated by FGD systems operated by electric utilities. Some gypsum companies have expanded or will be expanding synthetic gypsum use at existing wallboard plants as well. U.S. wallboard manufacturing capacity is expected to increase to 37 billion square feet (3.44 billion square meters) by yearend 2002 (Sharpe, 2001). At least a dozen wallboard plants in the United States were already using some synthetic gypsum to augment their feedstock from gypsum mines.

A portion of more than 4 Mt of gypsum waste, generated every year by wallboard manufacturing, wallboard installation, and building demolition, was recycled. The recycled gypsum was used chiefly for agricultural purposes and new wallboard. Other potential markets for recycled gypsum waste are in cement production, as a stucco additive, in sludge drying, in water treatment, in grease absorption, and for marking athletic fields (Turley, 1998; California Integrated Waste Management Board, September 2000, Drywall recycling, accessed August 1, 2001, at URL http://www.ciwmb.ca.gov/condemo/factsheets/drywall.htm).

Consumption

In 2000, the domestic construction industry leveled out, and some sectors declined. In 2000, housing starts declined by 4.38% compared with those of 1999. Apparent domestic consumption (defined as mine output plus reported synthetic used plus imports minus exports plus adjustments for industry stock changes) was about 34 Mt during the year. This was an

Digitized by Google

8.11% decline in U.S. gypsum consumption compared with that of 1999. Domestic sources (mining plus an estimated 4.95 Mt of synthetic gypsum) met approximately 73% of domestic consumption requirements; imports satisfied the remaining needs.

Gypsum output is categorized as either calcined or uncalcined (table 4). Calcined gypsum was produced domestically from crude gypsum to manufacture wallboard and plaster products during 2000. Uncalcined gypsum, used for portland cement production and agriculture, accounted for virtually all remaining consumption during the year.

In 2000, 42.7% of the calcined gypsum used to manufacture wallboard was consumed in the production of regular ½-inch wallboard. Fire-resistant wallboard, mobile-home board, water- and moisture-resistant board, lath, veneer base, and sheathing composed most of the balance (table 5). Metropolitan areas in the Atlantic and the Pacific coastal regions were the leading sales areas for gypsum wallboard products.

During 2000, most of the uncalcined gypsum consumed in the United States was used in portland cement production, and the remainder was used primarily in agriculture. Gypsum, which is added to cement to retard its setting time, accounted for about 2% to 5% of cement output (Dutton, 1997). Finely ground gypsum rock was used in agriculture and other industries to neutralize sodic soils, to improve soil permeability, to add nutrients, to stabilize slopes, and to provide catalytic support for maximum fertilizer benefits. Small amounts of high-purity gypsum also were used in a wide range of industrial operations, including the production of glass, paper, foods, and pharmaceuticals.

Prices

In 2000, the average values per metric ton (f.o.b. mine or plant) reported by U.S. producers were $8.44 for crude gypsum and $16.81 for calcined gypsum. The average value for plaster reported by domestic producers during the year was $5.57 per 100 pounds. In 2000, the average value of uncalcined gypsum used in agriculture and in cement production was $12.62 per metric ton.

During 2000, prices for gypsum wallboard generally decreased in response to decreased demand and supply. Prices for regular ½-inch wallboard dropped in 8 of the 20 major U.S. metropolitan areas that were sampled and remained the same in 7 of the 20. During 2000, the price changes from those of 1999 ranged from a decrease of $155 per 1,000 square feet to an increase of $129 per 1,000 square feet. Prices in these 20 U.S. cities ranged from $93 to $280 per 1,000 square feet at yearend (Engineering News-Record, 2000a, b).

Foreign Trade

In 2000, the United States was the world leader in the international trade of gypsum and gypsum products. The Nation imported crude gypsum from 11 countries (table 6), and exported gypsum wallboard to 70 countries and territories. U.S. imports accounted for most of the world's waterborne shipment of crude gypsum (Phillips, 1998). Only a small amount of crude gypsum was exported by the United States (table 7).

Net imports of crude gypsum in 2000, which decreased slightly from those of 1999, accounted for approximately 27% of apparent consumption. Much of this import dependence can be attributed to the lack of adequate domestic gypsum resources near large East Coast wallboard markets. These imports came primarily from Canada and Mexico. The two countries primarily supplied wallboard plants in coastal markets; most imports from Canada went to East Coast plants, and Mexican sources chiefly served the West Coast. Foreign subsidiaries of U.S. gypsum companies produced much of the gypsum that was imported for the wallboard plants. Smaller amounts of imported gypsum were used in portland cement production.

Wallboard exports, totaling about 69 million square feet (6.41 million square meters) and valued at $27 million, were primarily to countries and territories in Asia, Europe, and Latin America. Wallboard imports were about 932 million square feet (86.6 million square meters) valued at $113 million.

World Review

In 2000, 90 countries produced gypsum, 6 of which accounted for 57% of the total world production (table 8). Global gypsum production during 2000 is estimated to be approximately 106 Mt. More than 110 million metric tons per year of synthetic gypsum is generated worldwide (Roskill Information Services Ltd., 2000). The high demand for gypsum in the United States generated by the domestic construction industry was not matched abroad, with the exception of Canada and Mexico, which exported to U.S. markets. The estimate for world production is probably lower than actual because output that is used by the gypsum producers in some countries to make other products onsite was not reported. Additionally, production from small deposits in developing nations was intermittent and in many cases unreported.

As a low-value, high-bulk commodity drawn from deposits widely distributed throughout the world, gypsum tended to be consumed within the many countries that mine it. Less than 20% of the world's crude gypsum production was estimated to enter international trade. Only a few countries, such as Spain and Thailand, were major crude gypsum exporters. Australian exports were expected to grow when the development of a new mine at the world's largest known gypsum deposit on that country's west coast reached full capacity (Dickson, 1999). The proximity of large U.S. wallboard markets also has made Canada and Mexico significant gypsum exporters.

Although use of gypsum wallboard increased worldwide, only industrialized nations, such as the United States, used gypsum primarily for wallboard products. In developing countries (especially in the Middle East and Asia), most gypsum was used in the production of cement or as a plaster product.

Estimated world production capacity for gypsum wallboard in 2000 was at least 60 billion square feet (about 5.6 billion square meters) at more than 250 plants worldwide. About one-half of this capacity was in the United States, and Asia and Western Europe each accounted for about one-fifth. Plans to construct or expand dozens of wallboard plants were underway during the year in many countries throughout the world, including Brazil, Chile, China, Germany, India, Poland, and the United Kingdom (Ambolt, 1999; Dickson, 1999; Mullick, 1999).

Digitized by Google

As in the United States, the use of FGD gypsum by other industrialized nations, particularly in Japan and Western Europe, increased (Dickson, 1999).

Outlook

Housing starts for the second quarter of 2001 suggest that U.S. production and consumption may rise slightly or at least match the levels of 2000. Other supply-and-demand indicators, such as construction rates for new office and commercial buildings and the continuing trend to construct larger homes with more rooms, are also evidence that gypsum industry growth in 2001 will be at least level with 2000. As the Transportation Equity Act for the 21st Century (Public Law 105-178, enacted June 9, 1998), authorizing $219 billion for road building and repair through 2003, is further implemented, it will be an important stimulant for the domestic cement industry and for the use of gypsum in cement.

On June 25, 2001, U.S. Gypsum filed voluntary petitions for reorganization under chapter 11 of the U.S. Bankruptcy Code. This action was taken to resolve asbestos-related claims in a fair and equitable manner, while preserving U.S. Gypsum's asset base and ensuring its market position and reputation. During the restructuring period and beyond, U.S. Gypsum's operations will continue without interruption. It is the goal of U.S. Gypsum to address its asbestos liability through chapter 11, to complete its restructuring, and to emerge from chapter 11 as quickly as possible, with a comprehensive and final resolution (USG Corp., July 2001, USG Corporation—Restructuring information, accessed August 12, 2001, at URL http://www.usg.com/special).

During the next several years, the use of mined gypsum may decline significantly in the United States as greater quantities of synthetic gypsum supplant it in wallboard manufacturing. Some actual and planned mine closings already have been attributed to substitution by synthetic gypsum (Gersten, 1999). At least an additional 6 billion square feet (about 560 million square meters) of new wallboard capacity designed for synthetic gypsum feedstock is scheduled to come online by 2002 (Henkels, 1999). This rate of substitution seems likely to accelerate additional mine closings during the next decade.

The domestic gypsum industry is poised for a major change on the supply side. The appearance of very large capacity wallboard plants will trigger a major supply shift. As the U.S. gypsum industry undergoes this change towards large capacity wallboard plants supplied with synthetic gypsum, older, less efficient, and smaller, natural-gypsum-fed plants will find it increasingly difficult to compete. With prices declining, producers will continue to retire older capacity (Harris, 2001).

Industry trends also indicate significant developments abroad in the coming decade. For example, the pace and magnitude of wallboard plant construction in China indicates that China, with more than a billion potential consumers, could become one of the world's leading gypsum wallboard markets. Elsewhere, the extent of wallboard capacity growth in regions of Asia, Europe, and Latin America reveals that wallboard manufacturing is likely to become a more significant application of gypsum worldwide.

HELIUM

By Norbert Pacheco[1]

Grade-A helium (99.995% or better purity) sales volumes by private industry were 89.6 million cubic meters[2] (3,230 million cubic feet) in the United States in 2000 (table 1). Grade-A helium exports by private producers were 37.0 million cubic meters (1,330 million cubic feet) for total sales of 126.6 million cubic meters (4,564 million cubic feet) of U.S. helium, about an 8% increase from 1999. For 2000, domestic helium sales growth remained relatively stable. However, helium exports increased significantly. The increase in exported helium was mostly due to increased European demand for helium.

Legislation and Government Programs

The Federal Helium Program was established to provide all Federal agencies with current and estimated future helium needs to carry out Government programs authorized and funded by the U.S. Congress. The major Federal helium customers were the National Aeronautics and Space Administration, the U.S. Department of Defense, and the U.S. Department of Energy.

On October 9, 1996, the Helium Privatization Act of 1996 (Public Law 104-273) was signed into law. This legislation directed the Federal Helium Program to discontinue production and sale of refined helium by April 9, 1998. Some of the remaining key components of this legislation and applicable status updates are as follows:

- Dispose of all assets related to helium production, refining, and sales not later than 24 months after helium refinery closing.
  STATUS: A historical review was initiated in June 1999, and reports were completed in August 1999. The phase 1 environmental site assessment was initiated in early 1999, and reports were completed in July 1999. The National Park Service was preparing a historic architectural engineering report on the Amarillo and Exell Plants. Additionally, an application was been filed with the Texas Voluntary Compliance Program for the Landis property, and a contractor was secured for sampling and assessment. Property disposal actions continued.
- Begin selling Federal crude helium reserves in excess of 16.6 million cubic meters (600 million cubic feet) on or before January 1, 2005, and complete sales by January 1, 2015.
  STATUS: Crude helium sales (in kind) for helium that is sold

[1]Team Leader, Resources Evaluation, Bureau of Land Management, Amarillo Field Office - Helium Operations, Amarillo, TX.

[2]All metric helium volumes herein reported are at 101.325 kilopascals absolute (14.696 pounds per square inch absolute) and 15° C (59° F). Helium volumes, reported in parentheses following metric units, are measured in cubic feet at 14.7 pounds per square inch absolute and 70° F—1,000 cubic feet (14.7 pounds per square inch absolute and 70° F) = 27.737 cubic meters (101.325 kilopascals absolute and 15° C) and 1 cubic meter (101.325 kilopascals and 15° C) = 36.053 cubic feet (14.7 pounds per square inch absolute and 70° F).

Helium in the 20th Century

In 1900, helium was essentially unknown. Even though it was first detected during the solar eclipse of August 18, 1868, and it was found to exist in rather large quantities in natural gas wells of the midcontinental United States, commercial recovery of helium did not develop until the onset of World War I. At that time, the British Government became interested in helium as a lifting gas and initiated a research program at the University of Toronto. By 1918, a small experimental plant was operating near Hamilton, Ontario. When the United States entered World War I, the task of establishing a domestic source of helium was given to the U.S. Bureau of Mines. In 1921, the first full scale U.S. helium production plant was completed near Forth Worth, TX, where about 47 million standard cubic feet of helium was produced from the Petrolia Field. It operated until 1929. Because the U.S. Navy was using almost all of the helium produced in the country for the Airship Program, the Bureau of Mines built a new plant near Amarillo, TX, which could produce as much as 25 million cubic feet per year of helium. Later, the Bureau of Mines built the Exell plant, also in Texas, which eventually became its last operating plant. These two plants extracted helium from natural gas produced from the Government's Cliffside Field. Later, the Cliffside Field reservoir (also known as the Bush Dome) would become the only helium storage reservoir in the world.

In the 1950s, optimism about future markets for helium developed, and helium began to be considered as a resource during the cold war. Widespread use led to the Helium Act of 1960, which created the Helium Conservation Program, allowing for private helium production. As a result, five new private helium extraction plants were built over the next several years. From 1963 to 1973, the U.S. Government purchased helium from the private producers and stored it in Bush Dome. The helium industry continued to grow as more uses for helium were discovered. By 1996, 14 private companies owned a total of 20 helium plants, and U.S. helium consumption had grown to 2.6 billion standard cubic feet per year.

In 2000, the United States still led the world in helium production, accounting for about 80% of world output. Twelve U.S. private companies owned and operated 21 domestic helium production plants. U.S. helium consumption had grown to over 3.4 billion standard cubic feet per year, and demand for helium continued to grow worldwide. By then, helium uses included cryogenics, pressurizing and purging, welding, atmospheric control, leak detection, breathing mixtures, lifting, and medical applications.

Digitized by Google

to Federal agencies and their contractors by private companies began in January 1998. Open-market sales of crude helium were reviewed in a legislatively mandated study conducted by the National Academy of Sciences (NAS) concerning the impact on national, scientific, and military interests. The NAS study was completed in March 2000. Helium regulations, however, are being developed and, once in place, will be used to guide open-market sales of the crude helium.

- Continue operation of the helium storage field system, which includes the storage field and the crude helium pipeline used for storage and distribution of Government-owned and privately owned crude helium.
- Continue collection of helium royalties and fees from sales of helium extracted from gas produced from Federal lands.
- Continue helium resource evaluation and reserve tracking to monitor helium availability for essential Government programs.
- Complete land transfer to the Texas Plains Girl Scouts Council.
  STATUS: Historical and archeological reviews and environmental assessments were being carried out and were expected to be completed by August 2001.

Production

In 2000, 12 companies operated 21 privately owned domestic helium plants, 15 of which extracted helium from natural gas (table 2; figures 1, 2). All but two extraction plants used cryogenic extraction processes. The total sales of U.S. produced helium increased by 12.0% compared with that of 1999. All natural gas processed for helium recovery came from gasfields in Colorado, Kansas, Oklahoma, Texas, Utah, and Wyoming. During 2000, 11 private plants purified helium by using pressure swing adsorption technology. Nine privately owned plants that produced grade-A helium also liquefied helium. The plant operators and plant locations are listed in table 2.

Domestic production data for helium were developed by the Bureau of Land Management (BLM) from records of its own operations, as well as from its own high-purity helium survey, a single voluntary canvass of private U.S. operations. Of the nine operations to which a survey request was sent, 100% responded. Those data plus data from BLM operations represent 100% of the total helium sales and recovery data listed in table 3.

Domestic measured helium reserves and indicated helium resources as of January 1, 2000, were estimated to be 8.9 billion cubic meters (323 billion cubic feet). The resources include measured helium reserves estimated to be 4.1 billion cubic meters (147 billion cubic feet) in natural gas from which helium is being extracted. The measured reserves included nearly 951 million cubic meters (34.3 billion cubic feet) stored by the BLM in the helium storage conservation system. Measured helium reserves from indicated resources of natural gas with helium content greater than 0.05% are estimated to be 1.8 billion cubic meters (65 billion cubic feet). Indicated helium resources, a category of reserves slightly less certain than measured reserves, in natural gas with less than 0.3% helium were estimated to be 3.1 billion cubic meters (111 billion cubic feet). The majority of these indicated reserves were derived from the Potential Gas Committee designation of unconfirmed/probable reserves (Curtis, 2000, p. 2-3). Approximately 2.6 billion cubic meters (94 billion cubic feet), or 98% of the domestic helium reserves that are under Federal ownership from which helium is being extracted, is located in the Riley Ridge area in Wyoming and the Cliffside Field in Texas.

The changes in how the helium reserves have been reported above are meant to provide the reader a better view of the helium reserves from which helium is being extracted. The 4.1 billion cubic meters (147 billion cubic feet) is estimated helium reserves that can be extracted from natural gas production over the expected life of gasfields from which gas is currently being produced. The 1.8 billion cubic meters (65 billion cubic feet) is estimated measured helium reserves in gasfields, from some of which helium could be extracted in the future. The 3.1 billion cubic meters (111 billion cubic feet) is indicated helium resources in probable/unconfirmed natural gas resources from which helium is not likely to be extracted.

Most of the domestic helium resources are in the midcontinent and the Rocky Mountain regions of the United States. The measured helium reserves are in approximately 102 gasfields in 11 States. About 97% of these reserves are contained in the Hugoton Field in Oklahoma, Kansas, and Texas; the Panoma Field in Kansas; the Keyes Field in Oklahoma; the Panhandle West and the Cliffside Fields in Texas; and the Riley Ridge area in Wyoming. During 2000, the BLM analyzed 506 natural gas samples from 4 States in conjunction with its program to survey and identify possible new sources of helium.

Consumption

In 2000, private industry supplied 100% of the domestic demand. The major domestic end uses of helium were cryogenics (24.4%), pressurizing and purging (19.9%), welding (18.2%), and controlled atmospheres (16.0%). Minor uses included leak detection (5.6%), synthetic breathing mixtures (3.1%), and chromatography/lifting gas/heat transfer (total 12.8%) (figure 3). Cryogenics, specifically magnetic resonance imaging applications, dominated liquid helium use. Estimated 2000 domestic consumption by end use was based on a 1996 end-use survey conducted by BLM Helium Operations to determine the trends in helium usage.

New regulations, effective November 23, 1998, concerning in-kind crude helium sales were published in 43 CFR chapter II, part 3195. These regulations require that helium refiners selling to Federal agencies and their contractors must buy an equivalent amount of crude helium from the BLM. Such sales are referred to as "in-kind crude helium sales." In 2000, in-kind crude helium sales were 6.4 million cubic meters (231 million cubic feet) and were made by nine companies through contracts with the BLM.

Stocks

The volume of helium stored in the BLM helium conservation storage system, including the conservation pipeline network and the Cliffside Field, totaled 952 million cubic meters (34.3 billion cubic feet) on December 31, 2000. The storage system contained crude helium purchased under contract by the BLM from 1962 to 1973 and privately owned helium extracted by industry from natural-gas-supplying fuel markets and stored under contract. This and privately owned helium is returned to

Digitized by Google

the owners as needed for purification to supply private demand. During 2000, 23.3 million cubic meters (840 million cubic feet of private helium was delivered to the BLM's helium conservation system, and 51.9 million cubic meters (1,870 million cubic feet) was withdrawn for a net decrease of 28.6 million cubic meters (1,030 million cubic feet) of private helium in storage (table 4).

Transportation

Private producers and distributors shipped helium predominantly as a liquid in semitrailers. These semitrailers delivered the liquid helium to distribution centers where some of it was gasified and compressed into trailers and small cylinders for delivery to end users. The remaining liquid helium was sold as bulk liquid or repackaged in dewars of various sizes for delivery.

Prices

The price charged for crude helium to private companies for in-kind crude helium sales was $1.785 per cubic meter ($49.50 per thousand cubic feet) for fiscal year 2000.

Foreign Trade

In 2000, exports of grade-A helium increased to 37.0 million cubic meters (1.33 billion cubic feet) (table 1). Helium exports increased by 38.1% compared with those of 1999 and accounted for 29.2% of the U.S.-produced helium sales; private industry supplied all U.S. helium exports. The large increase in helium exports is attributed to increased European demand for helium. About 55% of the U.S. helium exports went to Asia, with Japan receiving about 71% of those exports. About 24% of the exported helium was shipped to Europe. Collectively, Belgium, France, Germany, and the United Kingdom received 94% of the helium exported to Europe. Other exports were as follows: Canada and Mexico, 8%; South America, 5%; Australia-New Zealand, 5%; the Middle East, 2%; Africa, Central America, and the Caribbean, less than 1% each. Import tariffs on helium established on January 1, 1998, remained at the 3.7% rate for normal-trade-relations nations and at the 25% rate for non-normal-trade-relations nations.

World Review

Excluding the United States, world production capacity of helium was estimated to be 29 million cubic meters (1.05 billion cubic feet). All known helium produced outside the United States was extracted in Algeria, Poland, and Russia (table 5).

Outlook

The total market for U.S.-produced helium increased by 8.2% compared with that of 1999. From 1995 to 2000, the market growth rate was about 5.7%.

Expansion of the Asian helium market over the next 2 years is expected to moderate owing to the uncertain economic conditions in that region of the world. Competition from foreign helium producers will provide continued uncertainty to the strength of the U.S. exports to the global helium market. Helium sales in the private sector are expected to continue at a moderate growth rate of 5% during the next 3 years. Use of high-temperature superconductor materials in electric motor windings and increased fiber optics demands are expected to increase helium demand.

INDIUM

By Robert D. Brown, Jr.

Domestic survey data and table were prepared by Carolyn F. Crews, statistical assistant.

Indium production in the United States during 2000 was confined to the upgrading of imported metal and the recycling of scrap. Two refiners, one each in New York and Rhode Island, were the major producers of indium metal and indium products in 2000. A number of smaller firms also produced high-purity indium alloys, compounds, solders, indium-tin oxide (ITO) coatings, and related products.

Domestic consumption was estimated by the U.S. Geological Survey to have increased moderately to about 55 metric tons (t) in 2000. Estimated uses were about the same as those in 1999, with stable consumption in all sectors except semiconductors, where there was a moderate increase. By sector, estimated consumption in 2000 was: coatings, 49%; solder and alloys, 33%; electrical components and semiconductors, 14%; and other uses, 4%. The value of primary indium consumed in the United States in 2000 was $10.3 million at an average producer price of $5.84 per troy ounce, calculated from prices published in Platt's Metals Week.

World consumption increased slightly in 2000. World refinery production was estimated at 220 t, a 2.3% increase compared with the 215 t (revised) produced in 1999. The six major producing countries were Belgium, Canada, China, France, Japan, and Russia. The recycling of indium, which became significant for the first time in 1996, was not significant domestically in 2000. However, recycling remains important in Japan (McCullouch, 2000). The increase in world consumption despite greater efficiency in the manufacture of ITO coatings with thin film transistor technology was due to increased demand for display devices and an increase in the production of indium phosphide, a semiconductor. Prices remained low despite strong demand, mostly owing to plentiful low-priced supplies from China (Mining Journal, 2000a).

World reserves, which are based on estimated indium content of zinc reserves, are sufficient to meet anticipated demand beyond the first decade of this century. Canada has greater resources of indium than any other country—about 27% of world reserves totaling 2,600 t. The United States holds about 12% of world reserves.

Legislation and Government Programs

The original National Defense Stockpile (NDS) goal for indium, set in 1989, was 41,990 kilograms (kg). In 1992, when the first purchase of indium was made for the stockpile, the goal was reduced to 7,740 kg. By 1996, as for many other commodities, the Annual Materials Plan for the NDS called for the elimination of indium from the stockpile. No sales were made in 1996, but stockpile disposals of indium amounted to 1,118 kg (35,956 troy ounces) in 1997, and (the last) 443 kg (14,248 troy ounces) in 1998. From that point on, the stockpile was depleted and the United States became completely dependent on imports for primary indium.

Production

U.S. production of primary indium in 2000 consisted of upgrading lower-grade and standard-grade indium (99.97% and 99.99%) into higher purity metal. Indium can be refined to purities up to 99.99999%. All of the indium to be upgraded was imported. Secondary production was mainly from new (unused, preconsumer) scrap and certain types of old (used, postconsumer) scrap. Nevertheless, only a small amount of indium was recycled domestically. Indium was produced in various forms, such as ingot, foil, powder, ribbon, shot, and wire.

Consumption

Domestic consumption in 2000 was estimated at about 55 t, a moderate increase from the 1999 level. Consumption in the various end uses held nearly steady, but semiconductor use increased. Thin-film coatings on glass, which included indium oxide and indium-tin-oxide, constituted almost one-half of total domestic indium use in 2000. The coatings, produced by sputtering the material onto a glass substrate, have been the largest area of research, development, and growth for indium in the past several years.

There are two kinds of indium-containing coatings—electrically conductive coatings and infrared-reflective coatings. Electrically conductive coatings, the more commercially significant group, are used primarily in liquid crystal displays (LCD) for watches, television screens, portable computer screens, and video monitors. They are also used to defog aircraft and locomotive windshields and to keep glass doors on commercial refrigerators and freezers frost-free. In addition, infrared-reflecting indium coatings on window glass limit the transfer of radiant heat through the glass, helping to make the heating and cooling of buildings more energy efficient.

About 33% of the indium consumed was used as an addition to combinations of bismuth, cadmium, lead, and tin to form low-melting-point alloys. These alloys are used in such applications as electrical fuses, fusible links, or as gripping material for the grinding of optical glass. Indium is used as a strengthening agent for lead solders and also as the base material for many low-melting-point solders. Indium-based solders have a number of advantages over ordinary solders: lower melting points, flexibility over a greater temperature range, and negligible leaching of gold components from electronic assemblies. Lead-free solders have been developed starting with indium-based alloys.

Indium is used in alkaline batteries to prevent the buildup of hydrogen gas in the sealed battery casing. These batteries are available in popular small consumer sizes, and together with semiconductors and other electronic uses, accounted for about

Digitized by Google

14% of the indium consumed domestically.

Prices

The domestic producer price as reported by Platt's Metals Week for 99.97%- to 99.99%-pure indium decreased from $6.22 per troy ounce at the beginning of 2000 to $4.58 per troy ounce at the end of the year; prices for higher grades of metal were not published. The price decline was a reflection of the world supply and demand situation. The average producer price was $6.22 per troy ounce at the beginning of the year. It held steady until early May, when it was lowered to $5.83 per troy ounce. The price fell again in October, first reaching $5.20 and then $4.58 per troy ounce (Platt's Metals Week, 2000b). The average indium price for the year was $5.84 per troy ounce.

The price for indium increased markedly in 1995 and then decreased just as markedly in 1996. Only modest fluctuations occurred in 1997. The price was nearly constant in 1998 and began a slow decline in 1999 which continued in 2000. The falling prices in 2000 were caused by good supply rather than poor demand. Chinese producers continued to sell at lower and lower prices, especially during the second half of the year. Higher purity indium is required for ITO, and Western indium producers were able to obtain a premium for their metal, creating a two-tier market (Platt's Metals Week, 2000c), but plentiful low-priced Chinese offers pulled down world prices (Platt's Metals Week, 2000e). One negative on the demand side was that demand was lower than expected from new Taiwanese consumers, manufacturing LCDs (Metal Bulletin, 2000a).

Trade

Imports decreased 10% by weight and 33% in value. For the first time China replaced Canada as the top supplier. These two provided 68% of the total. Next, in order of importance, were France, Russia, Peru, and Japan. Data on U.S. exports of indium were unavailable, but total exports were estimated at about 15 t.

World Review

Asia.—The world indium market in 2000 was dominated by a more than adequate supply from China. Japan remained the world's largest consumer of indium, with three-fourths of it going for ITO coatings. Low-priced indium was so readily available from China that prices remained low despite strong demand, especially in Japan (Mining Journal, 2000b, c).

Canada.—An interruption of indium production occurred at the Kidd Creek, Ontario, plant of Falconbridge Ltd. at the beginning of the year. A runout at a copper furnace combined with regular maintenance stopped production for 6 weeks, beginning in December 1999. Indium production was only reduced slightly (Mining Journal, 2000b).

China.—Chinese indium producers began to control sales in an attempt to prevent indium prices from falling further. Since indium is a byproduct of zinc, which must be produced continuously, the actual cost of indium production is low. Therefore, producers allow their stocks to increase rather than choose to curtail production, even if this creates a greater oversupply (Platt's Metals Week, 2000a).

Japan.—Indium demand reached a record 335 t in 2000 in Japan, with slightly more than one-half of the material coming from recycled scrap. ITO production increased 26% by weight over 1999 (Roskill's Letter from Japan, 2001b). Indium phosphide production increased 57% in value over 1999 (Roskill's Letter from Japan, 2001a).

Showa Denko K.K., already the world's leading producer of indium phosphide wafers using the metal-organic chemical deposition process, invested $29 million to triple its capacity at its Chichibu plant, northwest of Tokyo. Production of both indium phosphide epitaxial wafers and indium phosphide mirror wafers was expected to triple by mid-2001 (Furukawa, 2000a).

Owing to the booming electronics sector in Japan, Sumitomo Electric Industries Ltd. announced plans to expand its output of indium (and gallium and zinc) at its Itami plant, northwest of Tokyo. The materials produced are for compound semiconductors used in products like mobile phones (Platt's Metals Week, 2000d). Sumitomo also announced plans to establish new production facilities for indium phosphide and other semiconductors in the United States. The operation will produce gallium arsenide as well as indium phosphide (Furukawa, 2000b).

Taiwan.—Mitsui Mining & Smelting Co. Ltd. of Japan plans to build an ITO sputtering target plant in Taiwan. Taiwan is becoming one of the world's largest producers of the targets. The plant, a wholly owned subsidiary of Mitsui, is to be named the Taiwan Target Company and will be located near Taichung (Metal Bulletin, 2000b).

Current Research and Technology

In 2000, the growth rate for the thin film transistor LCD, which requires only one-third as much indium per unit as the supertwisted nematic (STN) LCD, was four times higher than that for the STN LCD. Since more than one-half of the world's indium consumption is for ITO coatings, the conversion to a more efficient technology has the same effect as would an increase in indium reserves.

Demand for indium phosphide wafers increased in 2000 for use in dense wavelength division multiplexing (DWDM) systems. These DWDM systems greatly increase the amount of information that can be transmitted on the Internet through optical glass fibers (Furukawa, 2000a).

At the Sandia National Laboratory of the U.S. Department of Energy, scientists researched uses and properties of indium gallium arsenic nitride semiconductor alloys. The addition of nitrogen to this system reduces gallium arsenide's bandgap energy requirement by one-third. The new material has potential for use in fiber optic lasers and communication satellites. As a part of a solar cell to provide power for space systems, this material could provide twice the efficiency of a standard silicon solar cell—up to 40%. A solar collecting package using this material would be smaller and lighter, providing increased payloads and cheaper launches. The utilization of this system for lasers makes it possible to adjust the gallium arsenide bandgap and provide a laser needed for short-distance fiber optics systems with greater manufacturing efficiency (Allan, 2000).

A new solar cell, based on a copper/indium/selenium compound has been developed in Germany. Cis-Solartechnik, GmbH, partly owned by Norddeutsche Affinerie AG, will continue development work on the new product, which is made

Digitized by Google

mostly by deposition through galvanic processes onto a flexible copper strip. The new cell, with greater than 10% efficiency, is light in weight and extremely tough (American Metal Market, 2000).

Outlook

Consumption of indium is expected to increase throughout the next decade, especially for LCDs, high-definition television, semiconductor materials, batteries, and low-temperature solders for military and electronic applications. The main driving force for this increase will continue to be Japanese production of LCDs using ITO and the production of telecommunications-use lasers and photo-diodes and other optic telecommunication systems using indium phosphide (Furukawa, 2000b).

Roskill predicted a world demand of 250 t by 2005 (Roskill Information Services, 1999). Japanese plus U.S. consumption of primary indium reached 225 t in 2000, mostly for ITO. Demand for indium needed for replacement nuclear control rods should remain steady, and that for fusible alloys and solders is likely to increase. If the price of indium rises sufficiently, recycling of the metal could increase in the United States and would tend to limit upward movements in price as long as a supply of appropriate scrap existed. Stocks of scrap increase when little recycling is occurring—as in recent years. World reserves, together with increases in production capacity (achieved through new plants and increased yields in primary recovery and improvements in manufacturing and recycling technology) are expected to be sufficient to meet the demand for indium beyond 2010.

However, other possible economic scenarios could diminish optimistic forecasts. For example, any slowdown of sales and profit growth in the telecommunications industry, which has been forecast by some industry observers, could significantly decrease indium demand (Berenson, 2001; Romero, 2001).

IODINE

By Phyllis A. Lyday

Domestic survey data and tables were prepared by John G. Durand, statistical assistant, and the world production table was prepared by Regina R. Coleman, international data coordinator.

Three producers of crude iodine supplied about 27% of domestic demand (table 1). Domestic and imported iodine was consumed in intermediate products prior to being sold to consumers (table 2). Iodine and derivatives find principal uses in pharmaceutical and medical applications, sanitation or disinfectants, animal feed, catalysts, inks, colorants, photographic equipment, and stabilizers. Published prices for crude iodine were unchanged from 1999 (table 3). Imports of crude iodine decreased by 7%, and imports of potassium iodide increased by 65% (table 4). End uses for domestic consumption in 2000 were reported in potassium iodide, which decreased by 26%, and sodium iodide, which decreased by 27%. Exports of crude iodine and potassium iodide were at 1999 levels during 2000 (table 5). Because some exports and imports are in product categories rather than crude products, net imports are not clearly distinguished. In Chile, iodine is a coproduct of sodium nitrate production. Japan produced iodine from brines associated with natural gas production (table 6).

Legislation and Government Programs

The Annual Materials Plan of the U.S. Department of Defense proposed the sale of 453,593 kilograms (kg) (1 million pounds) of iodine for fiscal year 2000. The National Defense Authorization Act for Fiscal Year 2000 (Public Law 106-65), signed on October 5, 1999, did not change the previous authorization for disposal of all stock of crude iodine in excess of the National Defense Stockpile (NDS) goal. The law authorized the transfers of no more than $150 million from the NDS Transaction Fund equally to the operation and maintenance accounts of the Army, Navy, and Air Force, no more than $50 million each (section 304). Public Law 106-65 also obligated no more than $78.7 million of the NDS transaction fund for the operation of the NDS program. The law required the sale of authorized commodities that would result in receipts of $10 million by the end of fiscal year 2000; $100 million during the fiscal year ending September 30, 2004; and $300 million during the fiscal year ending September 30, 2009. On October 17, 2000, the Defense National Stockpile Center (DNSC) issued "Amendment No. 003 to Solicitation of Offers for DLA-Iodine-003" that changed the dates for offerings to February 21, May 16, and August 15, 2001. On October 29, 1999, "Amendment No. 002 to the Solicitation" changed the sale of the 453,593 kg to quarterly sales of 113,398 kg (250,000 pounds) and set subsequent offering dates for 1999 and 2000. On January 13, 2000, the DNSC announced the award of 19,050 kg (42,000 pounds) at a value of $270,000 ($14.17 per kilogram or $6.42 per pound). On March 8, 2000, the DNSC announced the sale of 2,270 kg (5,000 pounds) at a value of $31,000 ($13.67 per kilogram or $6.20 per pound). On

Iodine in the 20th Century

Iodine was first produced in the United States between 1917 and 1921 at an experimental station at Summerland in Santa Barbara County, CA. Large quantities of seaweed were harvested and used to produce acetic acid, potash fertilizers, and iodine. Iodine was first exploited commercially in 1916 in the form of potassium iodide as a remedy for goiter. In 1916, tincture of iodine was used as a disinfectant for cuts and abrasions and for sanitation. In 1939, Louis Daguerre published details of his method for making photographs on plated silver by using iodine vapor to form a thin coating of light sensitive silver iodide crystals.

Iodine production from underground brines began in the United States on August 2, 1928, near Shreveport, LA, using a process developed by Dow Chemical Co. The General Salt Co. began extracting iodine in 1928 from oilfield brines in the Signal Hill district in Long Beach, CA, using a charcoal process. The Louisiana plant closed in 1932, and the operation moved to California and was renamed the Jones Chemical Co. Deepwater Chemical Co. produced iodine in California from 1932 until 1960 by the silver iodide process. Domestic production in 1937 was reported to be 136,000 kilograms. In 1938, the Jones plant was incorporated as the Io-Dow Chemical Co. Production in 1940 was 564,000 kilograms. In 1961, Dow closed its plant in California and opened an iodine plant in Midland, MI, using underground brines associated with bromine production. Dow closed its Michigan plant in 1986.

In 1977, Woodward Iodine Corp. began production of iodine in Oklahoma. This plant was purchased by Ise Chemical Industries Co. Ltd. of Japan in 1994. In 1983, North American Brine Resources completed two miniplants in Kingfisher County, OK. In 1987, IOCHEM Corp. opened an iodine plant in Vici, OK. All production in Oklahoma was from gas brines.

In 2000, iodine was consumed in animal feed (45%), pharmaceuticals (27%), catalysts (10%), heat stabilizers (5%), and other applications (5%). About 27% of the iodine consumed during 2000, which was about 1.5 million kilograms, was from domestic production.

Digitized by Google

June 7, 2000, the DNSC announced the sale of 2,270 kg (5,000 pounds) at a value of $30,000 ($13.23 per kilogram or $6.00 per pound). On August 31, 2000, the DNSC announced the sale of 14,300 kg (31,500 pounds) at a value of $188,000 ($13.21 per kilogram or $5.97 per pound). On December 5, 2000, the DNSC announced the sale of 11,200 kg (25,000 pounds) at a value of $150,00 ($13.23 per kilogram or $6.00 per pound). At yearend, 949,215 kg (108,500 pounds) was sold valued at $670,000, and the excess iodine was 1.7 million kilograms (Mkg) (3.8 million pounds) valued at $28 million ($16.44 per kilogram or $7.46 per pound).

In 1906, the Food and Drug Act was passed to ensure the safety and effectiveness of drugs and to set standards to determine which drugs can be sold over the counter and which ones require a prescription. During 1997 and 1998, online pharmacies were selling drugs to consumers without a valid prescription. Iodine and many of the products made from iodine are controlled substances. To protect consumers from illegal sales of drugs over the Internet, the Executive Office of the President unveiled an initiative in December that would require all online pharmacies to demonstrate that they comply with State and Federal laws and are licensed by the Food and Drug Administration (FDA). The maximum civil penalty would be raised to $500,000 from $1,000. The proposal would give the FDA subpoena power to investigate online pharmacies and provide $10 million to set up a rapid-response team to go after illicit drugs (Hileman, 2000).

One of the standards that is used for iodine is set by U.S. Pharmacopeia (USP). USP is an organization whose work is largely unknown, unrecognized, or overlooked by the public. USP sets and disseminates standards that ensure high-quality drugs for human and animal use, and it is a major element in drug regulation. The very foundation of drug regulation is delegated by statute to this private organization. USP was created in 1820 to bring some rational order to the pharmaceutical industry. At the first national convention, physicians made a list of safe and effective drugs and published this in what is now the USP. The USP was first revised in 1830 and every 10 years thereafter until 1970, when it was updated every 5 years; after 2002, it will be revised annually. In 1973, USP purchased the "National Formulary" (NF) from the American Pharmaceutical Association and combined the NF with the USP. The latest volume (USP24-NF19) was published in 2000 and included officially recognized standards for drugs and health care technologies (Ember, 2001).

Production

Domestic production data for iodine were derived from a voluntary survey of U.S. operations by the U.S. Geological Survey. The three companies to which a survey request was sent responded, representing 100% of the total production (tables 1, 6).

In 1987, IOCHEM Corp. began producing iodine by the blowing-out process at a plant 1.2 kilometers (km) east of Vici, Dewey County, OK. IOCHEM, the largest U.S. plant, was owned by the Kita family and Tomen Corp. The majority of the production was shipped to Schering AG of Germany under a long-term contract. IOCHEM reported having nine production wells and four injection wells with a total production capacity of 1,400 metric tons per year (t/yr) at Vici.

North American Brine Resources, owned by Beard Oil Co. (40%), Godoe Shigen (USA) Inc. (50%), and Mitsui & Co. (USA), Inc. (10%), began operating a miniplant at Dover in Kingfisher County, OK, in 1983. In 2000, the company operated one plant at an oilfield injection-disposal site that obtained brines from about 50 wells in the Oswego Formation. Iodine concentrations were as much as 1,200 parts per million (ppm). Its large plant in Woodward, OK, remained closed pending price increases.

Woodward Iodine Corp., which began production in 1977, was purchased by Asahi Glass Co. of Japan in 1984 and sold to Ise Chemical Industries Co. Ltd. of Japan in 1994. Woodward's plant in Woodward County, OK, produced iodine from 22 brine production wells, which used the blowing-out process, and injected waste through 10 injection wells. Mical Specialty Chemicals, Inc., a subsidiary of Mitsubishi International Corp., was the exclusive distributor for iodine produced by Woodward.

Consumption

Estimated end uses, by percentage, for iodine in 2000 were as follows: sanitation, 45%; animal feed, 27%; pharmaceuticals, 10%; catalysts, 8%; heat stabilizers, 5%; and other, 5%. Other smaller uses included inks and colorants, photographic chemicals, laboratory reagents, production of batteries, high-purity metals, motor fuels, and lubricants (table 2).

Commercial crude iodine normally has a minimum purity of 99.5%. Impurities are chiefly water, sulfuric acid, iron, and insoluble materials. The USP XVII specifies iodine content of not less than 99.8%. The Committee on Analytical Reagents of the American Chemical Society allows a maximum of 0.005% total bromine and chlorine and 0.010% nonvolatile matter.

Recommended daily allowances of iodine were as follows: infants, 40 to 40 micrograms (mg); children age 1 to 3 years, 70 mg, age 4 to 6 years, 90 mg, age 7 to 10 years, 120 mg, and age 11 and up, 150 mg; pregnant women, 175 mg; and lactating women, 200 mg. A quarter teaspoon of iodized table salt provides 95 mg of iodine. A 170 gram (6-ounce) portion of ocean fish provides 650 mg of iodine. Most people are able to meet their iodine requirements by eating iodized salt, plants grown in iodine-rich soil, seafood, and seaweed (Yahoo! Health, 2000, Iodine in diet, accessed October 30, 2000, at URL http://health.yahoo.com/health/diseases_and_conditions/disease_feed_data/iodine_in_diet).

In the human fetus, thyroid hormone is essential for the development of the central nervous system. The lack of thyroid hormone causes cretinism, which results in severe mental retardation and somatic growth. Until the 12th week of life, the sole source of thyroid hormone supply is maternal thyroid hormone. Recently, it was reported that the mild deficiency of thyroxine in maternal blood in the first or the second trimester of pregnancy would cause the impairment of cognitive capabilities of the offspring measured at 4 to 7 years after birth (Shishiba, 2000).

Arizona Chemical Division, which is a subsidiary company of International Paper Co., is a leading producer of pine chemicals

Digitized by Google

that include tall oil and rosins, which use iodine as a stabilizer. These pine products were used globally for a variety of end uses, including adhesives, chewing gum, inks and coating, lubricants, rubber, plastics soaps and cleaners, and other markets (Arizona Chemical, July 26, 2000, Arizona Chemical launched new Internet site, accessed August 14, 2000, at URL http://www.arizonachemical.com/press/press_internet_7-26-00.htm).

International Paper put its Arizona Chemical pine chemical business up for sale as one part of a divestment program. Arizona Chemicals, headquartered in Jacksonville, FL, celebrated its 70th anniversary on February 8 (Chemical Market Reporter, 2000b). With about $700 million per year in sales, Arizona Chemical is the world's largest pine chemical company, fractionating tall oil and turpentine into chemicals for the adhesive coatings and inks industries (Chemical & Engineering News, 2000).

Crude tall oil originates as tall oil soap, which is separated from recovered black liquor in the Kraft pulping process. The soap is then acidified to yield crude tall oil. The tall oil is fractionated to produce fatty acids, pitch, and rosin. The pulp and paper industry is mature, and companies are increasingly pulping younger farmed pine trees that have a lower chemical content. The use of recycled fiber has reduced the growth of Kraft pulp production, and hardwood pulping yields no tall oil. Some tall oil derivative customers that use adhesives have shifted from rosin to hydrocarbon resins to ensure adequate supplies. Because of increases in crude oil prices, many of those hydrocarbons have faced significant pricing pressure (Naude, 2000).

Fatty acids are sold in competition with vegetable fatty acids to producers of detergents, oilfield chemicals, and paints, or converted to derivatives, such as dimer acid. Rosin is almost always chemically modified into esters or adducts that are used to make adhesives, inks, and paper size. Hercules Inc. is the only company in the United States still extracting rosin and turpentine from aged pine stumps. Akzo and Hercules compete with products from China, because certain customers require the white high-purity rosins derived from Southeastern U.S. pine gum. Georgia-Pacific completed a 50% expansion of its tall oil fractionation capacity in Crossett, AR, reducing the amount of tall oil it sells on the merchant market. Westvaco Corp. is the fourth largest tall oil producer making speciality adhesive (McCoy, 2000).

Hercules acquired the pulp and paper division of Quaker Chemical Corp. The business generates $8 million per year in revenues and provides specialty chemicals for tissue papermaking and pulping processes (Chemical Market Reporter, 2000b). Hercules announced that it entered into discussions to sell its pine and hydrocarbon resin business to an unidentified "major company." Hercules sells about $450 million per year of resins and has 1,500 employees. Its product line is divided between resins made by refining crude tall oil, a byproduct of making paper from pine trees, and resins made from the 5- and 9-carbon hydrocarbons fractions that are produced in ethylene plants (McCoy, 2000). Eastman Chemical Co. announced its intent to purchase Hercules Inc.'s hydrocarbon resins business and select portions of its rosins resins business (Chemical Market Reporter, 2000a).

Radiopaque agents are drugs used to help diagnose certain medical problems. They contain iodine, which absorbs x rays. Radiopague-diagnosed medical problems include biliary tract disorders, brain disorders, cardiac disease, central nervous system disorders, cerebrospinal fluid, disk disease, gastrointestinal gall bladder disorders, peritoneal disorders, splenic and portal vein disorders, urinary track disorders, and vascular disease.

Perfluoroalky iodides are produced in a variety of chemicals, such as water and oil repellent finishes, surfactants, and surface-treatment agents. Another use is in the preparation of a functionally substituted perfluoro (vinyl ether), which is a key monomer for perfluorinated ion-exchange membranes for the industrial chlor-alkali industry. The amount of iodine used for these intermediates was expected to consume 1,500 metric tons (t) of world production in 2000 (Yamabe, 2000).

Prices

Prices for iodine are negotiated on long- and short-term contracts. The average declared cost, insurance, and freight (c.i.f.) value for imported crude iodine was $14.58 per kilogram. The average declared c.i.f. value for iodine imported from Chile was $14.38 per kilogram. The average declared c.i.f. value for imported crude iodine from Japan was $15.26 per kilogram. The average sale price of iodine sold from the DNSC was $16.44 per kilogram ($7.46 per pound). Published yearend U.S. prices for iodine and its primary compounds are listed in table 3.

Since 1977, when the first U.S. plant was built in Oklahoma, iodine c.i.f. prices per kilogram have been as follows: 1977, $4.39; 1978, $4.72; 1979, $6.57; 1980, $13.80; 1981, $13.12; 1982, $12.92; 1983, $12.06; 1984, $10.58; 1985, $11.86; 1986, $12.52; 1987, $15.26; 1988, $17.46; 1989, $17.67; 1990, $15.19; 1991, $10.16; 1992, $9.03; 1993, $7.90; 1994, $7.56; 1995, $9.88; 1996, $12.90; 1997, $14.66; 1998, $16.45; and 1999, $16.15. U.S. production decreased to 1.5 Mkg from 1.6 Mkg, and world production remained at 18 Mkg in 2000.

Iodine prices are stable compared to the volatility experienced during the 1980s and 1990s. In the second half of the 1980s, iodine prices increased as a result of strong demand and reduced supply owing to fire damage at iodine production facilities in Chile. Demand and prices decreased between 1990 and 1991. New capacity in Chile during 1996 and 1997 combined with increased sales from the DNSC caused an oversupply of iodine and a price decrease (Mineral Price Watch, 2001).

Foreign Trade

The U.S. Government adopted the harmonized commodity description and coding system as the basis for its export and import tariff and statistical classification systems. The system is intended for multinational use as a basis for classifying commodities in international trade for tariff, statistical, and transportation purposes. It includes resublimed and crude iodine under the same code and a free duty rate. Values that differ significantly could be a result of items being placed in the wrong category (tables 4, 5).

Digitized by Google

World Review

The worldwide production of iodine in 2000 was estimated to be approximately 18,000 t, of which 9,100 t (51%) was from Chile, and 6,100 t (34%) was produced in Japan. The industrial demands of iodine are still increasing, and areas of applications are expanding beyond the established markets, which are as follows: various additives (23%), x-ray contrast media (22%), germicides and disinfectants (17%), catalysts (15%), pharmaceuticals (9%), and other (14%) (Yamabe, 2000).

Azerbaijan.—This nation's economy is based on oil and natural gas production; oilfield brines contained iodine and bromine. Enterprises and individuals engaged in mineral extraction are subject to a mineral fields or subsoil tax. The tax is applied to the net income received from the sale of the product at rates ranging from 3% to 26%. According to the list approved by the Cabinet of Ministers in June 1996, the tax is applied to iodine and mineral water (Oil and Gas Chemistry, 2000).

The Neftchala iodine-bromine plant in Neftchala planned to conduct a tender to attract investment to modernize production to include production of potassium iodide and other iodine derivites. Investment of $1.4 million over 1.5 years is required. A production line for iodine-containing salt with a capacity of 100,000 t/yr has been constructed and commisssioned. The iodine is recovered from brines associated with the Neftchala and Khillinsky oilfields in the Prikurinsky Basin. The plant design capacity is 800 t/yr of iodine but is presently idle because of the need for capital for repairs (Industrial Minerals, 2000).

Chile.—Chile was the leading producing country of iodine. In response to falling prices and demand, Compania de Salitre y Yodo reduced its iodine output to 2,000 t/yr from 2,400 t/yr. DSM Mineraa SA cut production at the Iris-La Granja site by 30% in 1999. Sociedad Química y Minera de Chile SA (SQM) continued to idle two units.

Atacama Minerals Chile SCM, a subsidiary of Atacama Minerals Corp., Vancouver, Canada, finalized an agreement with ACF Minera S.A. to develop the Aguas Blancas project near Antofagasta, Chile. The agreement includes plans for a larger capacity heap-leach operation to allow for production of 720 t/yr. Once the iodine facilities are operational, the plant will begin production of the potassium nitrate and sodium sulfate reserves (Mining Engineering, 2000).

The nitrate and iodine project at Pampa Dominador was being developed by Minera CeroImán SCM (MCI), a wholly owned subsidiary of Minera Soledad S.A., a Chilean private company established in 1988. The deposit is located within the Atacama Desert at an altitude of 1,750 meters (m) and 160 km southeast of the Pacific port of Antofagasta. The site is the location of the former Oficina Salitrera Dominador, which operated from 1925 to 1930. A total of 8,750 hectares (ha) of MCI's mining property at Pampa Dominador is the main deposit for the nitrate and iodine project. An export program that covered about 5,000 ha was carried out during 1998. Nine ore bodies with average ore strata thickness of 2 m and overburden thickness averaging 0.6 m were defined. Reserves calculated to January 1999 included proven reserves of 540 Mkg of iodine with probable reserves of 620 Mkg iodine (Minera CerroImán, 2000).

The Potash Corporation of Saskatchewan, Inc. (PCS) began production from the Yumbes Mine in July. About 18 t of iodine was shipped from the mine to the United Kingdom. Planned production will include 40 t/yr of iodine. PCS has put about $14 million into the projet since acquiring the project for $36 million in 1999 (Green Markets, 2000).

Cosayach S.A. was preparing to begin production of nitrates at its operation near Poao Almonte in the northern Chile. Production also included limited amounts of iodine (Fertilizer Week, 2000).

All of SQM's production was from surface mines at Pedro de Valdivia and Maria Elena and from mine tailings at Sierra Gordo. Exports of 80% of the iodine produced go to the following areas: Europe (40%), the United States (27%), South America (21%), Asia (7%), and Africa (5%) (Eugenio Ponce, International Fertilizer Industry Association, 1998, Chile—Specialty fertilizers and industrial chemicals from two unique resources, accessed May 23, 2001, at URL http://www.fertilizer.org/publish/biblio/biblio99/conf4.htm).

Three of SQM's top officials were fined a total of $32,000 by Chile's Superintendencia de Valores Y Seguros (SVS). The SVS alleged that the president of Ora Blanco did not inform the Commission that they had set up two companies that held ultimate control of SQM. Patco Trust and Holywell Trust were registered in the British Virgin Islands in 1994 but were not declared to the SVS until 1999 (Industrial Minerals, 2001).

All iodine processed in Chile uses sulfuric acid. The use of a sulfuric-acid-nitrate mixture could generate fumes and leakages, with inherent risk to the workers. Sulfur melting and sulfur dioxide generation was performed using the same technology in all Chilean plants. Only the age of the plant makes the difference in emissions to the atmosphere. Using kerosene in a solvent extraction process puts plants at increased risk of fire (Munoz, 2000).

India.—The duty on iodine was reduced to 10% from 25%. The chemical industry has become a major producer and exporter of chemicals in the world partly because of scaling down the import duty on chemicals widely used in the industry (Ministry of Finance,1997, Public finance—Tax measures, accessed January 17, 2001, at URL http://finmin.nic.in/indiabudget/es97/CHAP2.htm).

Indonesia.—P.T. Lamindo Ekaperdana reported brines containing 100 ppm of iodine. The company planned to build a 250 t/yr iodine plant (Tampi Mariko, P.T. Lamindo Ekaperdana, written commun., 2000).

Japan.—Japan was the world's second largest producer of iodine (table 6). Iodine was manufactured in Chiba, Miyazaki, and Niigata Prefectures; Chiba Prefecture accounted for about 90% of all production in Japan. The following 8 companies operated 11 plants in Japan during 1999: Ise Chemical Co, Ltd. 2 plants in Chiba Prefecture and 1 in Miyazaki Prefecture, 300 metric tons per month (t/mo); Kanto Natural Gas Development Co., Ltd. (KNG), Chiba Prefecture, 100 t/mo; Godo Shigen Sangyo Co., Ltd., Chiba Prefecture, 200 t/mo; Japan Energy Development Co., Ltd., Niigata Prefecture, 30 t/mo; Teikoku Oil Co. Ltd, Chiba Prefecture, 50 t/mo; Toho Earthtech, Inc., Niigata Prefecture, 60 t/mo; Nippoh Chemicals Co., Ltd., Chiba Prefecture, 60 t/mo; and Nihon Tennen Gas Co., Ltd., 2 in Chiba Prefecture, 100 t/mo.

Digitized by Google

Sumitomo Chemical Co. and Mitsui Chemicals Inc. announced a $1.6 billion merger targeted for 2003. This would create the largest chemical company in Asia and fifth largest in the world. Mitsui is a producer of iodine in the United States. Mitsui and KNG have a joint venture (JI Chemicals, Inc.) to develop iodine derivative products (Kanto Natural Gas Development Co., Ltd.).

KNG was established in 1931 and uses the ion-exchange resin and the blowing-out method to produce iodine. In the ion-exchange resin method, sand and other impurities are removed by precipitation or filtration. The iodine is then separated from the brine by means of an oxidizing agent and collected by adsorption on the ion-exchange resin. The iodine is separated from the resin by elution, then is crystallized and refined. The blowing-out method makes use of the ease with which iodine evaporates and is suitable for use with high-temperature brine. After removal of sand and other impurities by precipitation and separation of the iodine using an oxidizing agent, the brine is exposed to air. The iodine evaporates and is then absorbed, crystallized, and refined. The brines average 110 ppm and the iodine produced is 99.7% pure. International Standards Organization (ISO) 9002 certification was granted in 1995 (Kanto Natural Gas Development Co., Ltd.).

Nihon was established in 1940, and iodine production began in 1944. In 1969, a new plant was built in Yokoshiba-machi, and in 1973 and 1988, new plants were built in Chiba Perfecture. Equipment for iodine adsorption changed to sloping fluidized bed (SFB) in June 1993. The plant gained ISO 9002 certificiation in 1996. The iodine was produced by two processes: the extraction by resins discussed before and the SFB developed to pass brine through the adsorption tower without filtration. The elution of the resin produces a concentrated iodine solution. Iodine is crystallized by oxidizers and is separated and refined into a flaked product (Nihon Tennen Gas Co., Ltd.).

The Forum on Iodine Utilization (FIU), which was created in June 1998 with the cooperation of industrial, governmental, and academic circles, reached 300 members in 1999. The FIU actively promotes the development of the iodine industry by a variety of symposiums on basic research and applications. The third FIU symposium was held at Chiba University in 2000. It included 17 talks and 30 poster sessions.

Iodine deficiency disorder (IDD) occurs in areas where iodine content in food is very low. Developed countries have realized the problem and require iodized salt for consumption. In 1986, a representative of Japan attended the International Council for Control of Iodine Deficiency Disorder's inaugral meeting in Nepal. A common agenda was established between Japan and the United States in 1996 to promote cooperation on IDD problems. The Japan International Cooperation Agency and the government of Chiba Prefecture started the Assistance for Mongolia Program in 1997 (Irie, 2000).

Recent studies on iodine in brines from the late Pliocene age (a period between 5 and 1.8 million years ago) in Kazusa Formation in Chiba, Japan, showed that the iodine orginated during the Palaeogen age, a period in the Cenozoic Era between 65 to 54 million years ago, which is much older that the layers in which the brines occur. The results might indicate that iodine in these brines is not derived from the reservoir formation but is released from marine sediments undergoing subduction in this region (Muramatsu, 2000).

Russia.—Iodine content ranges from 30 to 90 milligrams per liter in 20 oilfields of Northern Sakhalin. The highest grade field is the Odoptu field where recovery of the iodine content could produce 30 metric tons per day of iodine (Elena Sabirova, American Business Center, written commun., March 19, 2001).

Turkmenistan.—Iodine is produced in Turkmenistan and Azerbaijan from underground brines. The Nebitdag plant was in Vyshka, 26 km southwest of Nebitdag City in Balkan Velayat. The plant extracts bromine and iodine from underground brines of the Nebitdag-Monjoukley deposit. The plant reported production capacities of 255 t/yr of iodine and 3,200 t/yr of ferrous bromide, as well as 1,300 t/yr of bromine derivatives and 100 t/yr of sodium hypochlorite. It was commissioned in 1969 and had 33 employees (table 6).

Current Research and Technology

Three scientist received the Nobel Prize in Chemistry for developing the important new field of electrically conductive polymers. The polymer was produced in 1977. By doping polyacetylene with iodine, the polymer film conductivity increased. On exposure to iodine, polyacetylene is oxidatively doped, and the polymer chain loses an electron, leaving a hole or positive charge. When the hole is filled by an electron jumping from a neighboring position, a new hole is created. As the cascade continues, the positive charge can migrate down the conjugated chain (Dagani, 2000).

Researchers at the Massachusetts Institute of Technology devised a coating, hexyl-PVP, that can kill 99% of common disease-causing organisms. PVP is the acronym for polyvinylpyrrolidone. The polymer kills bacteria by a powerful chemical-electrical action, a permanent positive charge that destroys bacterial cell walls and membranes. The antibacterial coating could be incorporated during manufacture so that the surface of many products could be permanently sterile (Midfully.org, May 22, 2001, Hexyl-PVP special coating kills germs, researcher says, accessed June 28, 2001, at URL http://www.mindfully.org/Plastic/Hexyl-PVP-Kills-Germs.htm).

PVP polymers (PVPP) are dye-receptive agents, binders, complexing agents, detoxicants, film formers, stabilizers, protective colloidal, and suspending agents. The polymers are available in several viscosity grades, ranging from very low to very high molecular weight, giving this family of products great flexibility across a wide range of industries (International Specialty Products Corp., 1999, PVP polyvinylpyrrolidone polymers, accessed January 22, 2001, at URL http://www.ispcorp.com/products/industrial/ind11.html).

International Specialty Products Corp. (ISP) offers a tablet disintegrantor that is based on PVPP technology similar to that used by pharmaceutical tablet formulators. The PVPP swells on contact with water, causing rapid tablet breakup and helping soap to dissolve quickly in the wash. ISP is planning a series of blends of PVPP with other disintegrant materials to offer a range of cost and performance options (McCoy, 2001).

Researchers at the Chiba Institute of Technology developed an aluminumoxidation coating impregnated with an iodine compound by an electrochemical method. The bactericidal

Digitized by Google

activities of the coating were effective against various molds and bacteria (Takaya, 2000).

The adsorpiton of iodine on single crystal electrodesis is one of the most intensively studied electrochemical processes. Recent studies at Tohoku University disclosed a novel property of iodine-modified electrodes because the adsorption of organic molecules formed highly ordered molecular arrays. The internal molecular structure, orientation, and packing arrangement were clearly visualized with near-atomic resolution by in situ scanning tunneling microscopy (Itaya, 2000).

Hydrogen iodide gas showed superior characteristics for etching materials, such as indium tin oxide (ITO) film, used for pixel electrodes of liquid crystal displays. Although wet etching is still the major process for ITO etching, the dry etching process makes sharper etching compared with other gases (Sadamoto and others, 2000).

Iodine-125 is the primary radionuclide for in vitro application due to its 60 day half-life and low energy photon emission. The long half-life permits the preparation of radioimmunoassay and immunometric radioassay. Iodine-123 has good imaging properties for planar and single-photon emission computed tomography imaging. Its physical properties include a half-life of 13 hours. Iodine-131 has a relatively long half-life (8 days) and emits both gamma and beta rays, which render this radionuclide useful for in vivo radiotherapy of cancer and Basedow's goiter. Iodine-123 and iodine-131 also are applied to label such proteins as antibodies against tumor cells for both external imaging and targeted radiotherapy. Monoclonal antibodies have been used to deliver radionuclides to target tissues for diagnostic and therapeutic purposes. The use of radiolabeled intact antibodies has shown limitations, such as slow penetration into tumors. Studies at Chiba University indicated that an iodine organic reagent (HML) would be a promising reagent for targeted imaging and therapy using antibody fragments as vehicles. These studies suggested that radiochemically designing antibody fragments that liberate radiometabolites of urinary excretion by the action of brush border enzymes may constitute a new strategy for reducing the renal radioactivity levels of antibody fragments (Arano, 2000).

Chemists at the Massachusetts Institute of Technology found that a chiral catalyst derived from 4-pyrrolidinopyridine and O-acylated azlactone exhibits the correct reactivity for catalytic kinetic resolution of racemic primary amines. The iodine catalyst reacts more rapidly with the catalyst than the amine, allowing the catalyst to exert its chiral influence before the reaction is complete (Chemical & Engineering News, 2001).

Evergreen Nylon Recycling llc (ENR) was named Recycler of the Year by the Plastics Recycling Division of the Society of Plastics Engineers. ENR is a joint venture of Honeywell International Inc. and DSM Chemicals North America Inc. The company converts postconsumer nylon-6 carpet and other nylon-6 waste that required iodine compounds as a stabilizer during manufacturing into caprolactam, the raw material for nylon-6. Type 6 nylon is used in products that include automotive parts, residential and commercial carpets, engineered plastics, films, packaging, and sporting goods (Reese, 2000).

At the 198th meeting of the Electrochemical Society in Phoenix, AZ, 1,200 scientific presentations were presented, including one on the use of lithium-iodide batteries. The plenary lecture focused on electrochemistry in the service of medicine. The vice president of research and development at battery manufacturer Wilson Greatbatch, Clarence, NY, gave an overview of power sources used in implantable medical devices. Nearly all pacemakers being implanted today run on lithium-iodide batteries, and the cells are extremely stable with some real-time tests showing these batteries running continuously for nearly 25 years. The life expectancy of the battery is determined by its size (Jacoby, 2000).

Chemists at the University of Lausanne, Switzerland, have invented an asymmetric carbon-carbon bond-forming reaction that could be useful in synthesis. Methyl iodide is used in part of the reaction (Stinson, 2000).

Scientists at the National Institute of Radiological Science (Japan) and Geochemisches Institut (Germany) analyzed 300 rocks and major units and subunits of the Earth's crust for iodine. The high average concentrations were 30 ppm of iodine in deep-sea carbonates and 2.5 ppm iodine in continental limestones. Seawater averaged 50 parts per billion iodine (Muramatsu and Wedepohl, 1998).

At a session of the American Chemical Society's national meeting in San Francisco in March 2000, European researchers presented data confirming that a wide variety of drugs and their metabolites are showing up in low concentrations in waterways of Croatia, Germany, Greece, and Switzerland. One of the pharmaceuticals identified in the environment is iopromide, an x-ray contrast media. Pharmaceuticals and personal care products can end up in the environment if not properly disposed. In the United States, the topic falls within the regulatory responsibilities of the U.S. Environmental Protection Agency and the Food and Drug Administration (Zurer, 2000).

Outlook

During the past decade, iodine production capacity in Chile and the United States has doubled, thus ensuring an adequate future world supply. Overall growth in traditional uses is projected to grow by as much as 2% per year. Uses for iodine in specialty chemicals have remained stable.

Recent developments in digital imaging can produce electronic prints and overhead transparencies without the need for wet processing. By using a digital camera or scanning the film and converting to digital tapes, the images are produced and stored on disks, hard drives, and tape. Digital imaging is used for recording most sporting events, game shows, and some situation comedies for television broadcast. From 75% to 85% of all televised programs seen during prime time are recorded on 35-millimeter (mm) motion picture film and then transferred to video tape or laser disc for display. Furthermore, the majority of feature films for movie theater presentations are shot and printed on film because of better image quality. A frame of 35-mm color negative film contains about 6.6 million pixels, about 15 times that of the best high-definition television system and 4 times that of the digital systems now in development. Most popular home video rentals have been box office movie hits that were filmed and then transferred to video. In the next decade, future uses of iodine in films and processing could be limited to specialty imaging as digital imagery technology

Digitized by Google

improves and the cost of equipment becomes more affordable.

New uses of fluoroiodocarbon as halogen replacements may cause an increased demand for iodine. More tests need to be completed on the iodated fluorocarbons before they are acceptable, but preliminary tests are promising. Supplemental programs designed to alleviate iodine deficiency disorder in China and India are consuming large amounts of iodine. X-ray contrast media, which contain as much as 60% iodine, will continue to grow between 4% and 5% per year. In Chile and Mexico, individual water purification units that use iodine are a new application of a historical purification process. Purification applications could become significant consumers of iodine.

IRON AND STEEL

By Michael D. Fenton

Domestic survey data and tables were prepared by Nicholas Muniz, statistical assistant, and the world production tables were prepared by Linder Roberts (pig iron) and Ronald L. Hatch (steel), international data coordinators.

The U.S. steel industry was adversely affected by the 1997 Asian financial crisis as Asian demand for steel and ferrous scrap declined, Asian currency exchange rates declined, and inexpensive steel became available for export to U.S. markets from excess Asian steel-producing capacity. Domestic steel product manufacturers welcomed inexpensive imports, but domestic steel producers were forced to reduce production and scrap consumption, which led to an oversupply of scrap and a plunge of steel and scrap prices. Through 1999, the steel-producing and scrap industries were on the rebound owing primarily to resurging Asian economies and increasing steel demand in Asia and the United States. As 2000 began, steel producers and scrap suppliers were increasingly optimistic that they were on track for a slow but certain recovery to precrisis economic levels. However, to the detriment of these sectors, the U.S. 117-month economic expansion—the longest in U.S. history, beginning in March 1991—was showing signs of weakening. The nation's economy displayed an annual growth rate of 5.2% in the first half of the year, 1.6% in the second half of the year, and only 1% in the fourth quarter—the weakest performance since the second quarter of 1995 (Leo Kamp, The 2001 economy overview, TIAA-CREF Web Center, accessed October 12, 2001, at URL http://www.tiaa-cref.org/siteline/archive/gen0104_065.html). Concurrently, prices of electricity and natural gas were increasing significantly, and steel imports, which declined in 1999 below the 1998 level, began to increase again in 2000. Prices for steel products and ferrous scrap again plunged to record levels. Although for relief the U.S. steel industry filed trade cases against dumped hot-rolled carbon steel from 11 countries, it was becoming clear that a more fundamental problem was that the world had excess steelmaking capacity. Steelmakers can produce 15% more steel than the world market demands, but are adding 2% more capacity each year (Iron and Steelmaker, 2001; Matthews, 2000). Data regarding U.S. production of iron and steel and shipments of steel mill products were reported by the American Iron and Steel Institute (AISI). These data can be regarded as representing 100% of the raw steel producers in the United States. World production of iron and steel is reported by the International Iron and Steel Institute (IISI) and by foreign government agencies. Consistent with international usage and Federal Government policy, the U.S. Geological Survey reported all data on iron and steel in metric units, unless otherwise noted.

Environment

In December, the U.S. Environmental Protection Agency (EPA) proposed new waste water release and treatment standards for iron and steel manufacturing facilities involved in cokemaking, ironmaking, integrated and nonintegrated

Steel in the 20th Century

By early 1900, the United States led the world in steel production contributing about 36% of the world's output, followed by the German Empire (23%), the United Kingdom (17%), and Russia (10%). The Bessemer, open hearth, and crucible furnaces were used in the United States for 67%, 32%, and 1%, respectively, of steel production. Iron and steel scrap was usually 45% to 55% of the charge used in open hearth furnaces, although a 100% scrap charge was possible. Industries in the United States entered a period of extraordinary prosperity beginning in 1899. Labor, both skilled and unskilled, had never been in greater demand in the United States, and wages increased significantly. Demand for all types of manufactured products increased as labor wages increased, and mills and factories operated at their fullest capacities to satisfy demand. The steel industry shared in this prosperity because it satisfied a growing demand for steel in consumer goods; locomotives, rail cars, and rails for expanding railroads; railroad and road bridges; ships; public buildings; electricity generation plants; and water supply facilities. Imports of steel mill products (1.8 million tons) exceeded exports (0.7 million tons) as domestic demand for U.S. steel increased and European demand decreased.

In 2000, the United States ranked third in the world as a producer, accounting for 12% of world production. The steel production of China and Japan exceeded that of the United States with 15% and 13% of world output, respectively. The Bessemer, open hearth, and crucible furnaces were replaced in the steelmaking process by the basic oxygen and electric arc furnaces, which made 53% and 46% of U.S. steel production, respectively. The charge of the electric arc furnaces was usually nearly 100% iron and steel scrap. January 2000 marked the 105th month of an unprecedented period of economic growth, during which U.S. industry, including the steel sector, successfully met the challenges of high domestic demand and global competition. The prosperity of steelmakers was marred when declining Asian demand for steel, excess Asian steel-producing capacity, and unusually low steel prices that began with the Asian financial crisis of 1997 brought about a major influx of steel from Asia to the United States. Imports of steel mill products (34.4 million tons) exceeded exports (5.9 million tons) in 2000 and accounted for 29% of U.S. apparent consumption of steel. Domestic steel producers sought relief in the form of tariffs and quotas imposed by the U.S. International Trade Commission in an effort to reduce imports.

Digitized by Google

steelmaking, steel finishing, direct-iron reduction and briquetting, and forging (Bourge, 2001). EPA estimates that the changes would reduce pollution by at least 952,000 metric tons per year with the value of benefits ranging from $1.1 million to $2.7 million. Estimated compliance costs range from $56.5 million to $61.4 million per year.

Production

Production of raw steel in the United States increased to 102 million metric tons (Mt) from 97.4 Mt in 1999 (table 1). AISI estimated raw steel production capability to be 118 Mt, up from 116 Mt (revised) in 1999. Production represented 86.1% of estimated capability, compared with 83.8% in 1999.

Integrated steel producers smelted iron ores to liquid iron in blast furnaces and used basic oxygen furnaces to refine this iron with some scrap to produce raw liquid steel. The basic oxygen process was used to make 54.0 Mt of steel (American Iron and Steel Institute, 2000, p. 74). The use of this process declined slightly to 53.0% of total steel production in 2000 from 53.8% in 1999. The integrated steel industry in the United States consisted of 13 companies operating ironmaking and steelmaking facilities at 19 locations (Iron and Steelmaker, 2000). Several of these companies also operated nonintegrated plants and/or other steelmaking facilities at the same locations.

Minimills and specialty mills are nonintegrated steel producers that use electric arc furnaces (EAFs) to melt low-cost raw materials (usually scrap). They also employ continuous casting machines and a hot-rolling mill that are often closely coupled to the casting operation. Specialty mills include producers of stainless, alloy-electrical, and tool steel; high-temperature alloys; forged ingots; and other low-volume steel products. The nonintegrated sector of the industry, 79 companies having 120 steelmaking plants, used the EAF steelmaking process to produce 47.8 Mt of steel, an increase of about 6% compared with that of 1999, and accounted for 47% of total steelmaking (American Iron and Steel Institute, 2000, p. 74; Iron and Steelmaker, 2001).

Raw liquid steel is mostly cast into semifinished products in continuous casting machines. Only 3.6% of U.S. production was cast in ingot form and subsequently rolled into semifinished forms; this represented a decrease of nearly 8% compared with that of 1999. Continuous casting production was 98.1 Mt, or 96.4% of total steel production, compared with 93.4 Mt, or 95.9%, in 1999 (American Iron and Steel Institute, 2000, p. 75).

Consumption

Steel mill products are produced at a steel mill either by forging or rolling into forms normally delivered for fabrication or use. Some companies purchase semifinished steel mill products from other steel companies and use them to produce finished steel products. To avoid double counting steel mill product shipments under these circumstances, steel mills identify any shipments of steel mill products to other companies that are reporters of steel mill product shipments. The accumulated shipments of all companies less the shipments to other reporting companies are identified as "net" shipments.

The 6-year trend of steadily increasing net shipments of steel products to satisfy domestic demand ended in 1998, but resumed its upward course in 1999 and 2000 (American Iron and Steel Institute, 2000, p. 27). Shipments of steel mill products by U.S. companies increased by 2.7%, to 98.9 Mt, compared with those of 1999. Export shipments by AISI reporting companies increased to 5.9 Mt from 4.9 Mt in 1999 (American Iron and Steel Institute, 2000, p. 45). Shipments to domestic customers increased by 2.3% during 2000 (American Iron and Steel Institute, 2000, p. 30). Shipments of construction and contractors' products, the largest single end-use market, increased 10%. Automotive product shipments decreased by 4.2%. Oil and gas, mining, quarrying, and lumbering industries shipments increased by 29%. Shipments of industrial and agricultural machinery, equipment, and tools decreased 8.4%. Steel service center shipments, appliance shipments, and containers, packaging, and shipping material shipments increased by 5.9%.

Prices

The Bureau of Labor Statistics Producer Price Index for steel mill products was up 3% to 108.4 from 105.3 in 1999 (1982 base=100) (Bureau of Labor Statistics, Producer Price Index-Commodities, accessed June 17, 2001, at URL http://146.142.4.24/cgi-bin/surveymost). The index increased steadily from about 105 throughout 1999 to a high of 110.2 in May 2000 and then decreased steadily to 105.5 at the end of 2000.

Foreign Trade

Exports of steel mill products increased to 5.9 Mt from 4.9 Mt in 1999 (American Iron and Steel Institute, 2000, p. 45). Canada again received the largest amount of U.S. exported steel, 3.8 Mt, up from 3.2 Mt in 1999. Mexico was again in second place, receiving 1.3 Mt, up from 1.1 Mt in 1999. Imports of steel mill products increased by 6.1% to 34.4 Mt from 32.4 Mt in 1999 (American Iron and Steel Institute, 2000, p. 55) . Brazil, Canada, the European Union (EU), Japan, the Republic of Korea, Mexico, and Russia were major sources of steel mill product imports.

Despite rising domestic steel mill capacity, imports of steel mill products have increased 140% since 1991 and imports of semifinished steel have nearly tripled. Domestic producers have been unable to keep up with demand for semifinished products and finished steel, and an unfavorable currency exchange rate has made foreign steel prices much more competitive. Although U.S. steelmakers have viewed imported finished steel as competing directly with domestic products, imports of semifinished products have not been perceived as rivals. This dichotomy is based on the need for imported semifinished steel to make up for the domestic shortage of hot-metal capacity to satisfy the U.S. market demand for finished steel mill products.

Imports of semifinished steel by steel companies must be taken into consideration in evaluating apparent consumption (supply) of steel mill products in the United States and the share of the market represented by imported steel. To avoid double counting the imported semifinished steel and the products produced from it, the amount of semifinished steel consumed by companies that also produced raw steel must be subtracted from domestic consumption. Between 1993 and 1998, annual imports were estimated to be 2.5 Mt to 7.8 Mt. Prior to 1993, the annual amount was less than 0.2 Mt. By taking the import semifinished steel into consideration, the share of the U.S. steel market represented by imported steel was an estimated 29% in 2000 compared with 28% in 1999.

Regarding the reporting of imports and exports, "fabricated steel products" are produced from steel mill products, but do not

Digitized by Google

include products that incorporate steel products with other materials. Examples of fabricated steel products are fabricated structural steel and steel fasteners. "Other iron and steel products" refer to products that are not produced from steel mill products. Examples of other iron and steel products include iron or steel castings and direct reduced iron (DRI).

The year 1997 was the first time the AISI reported an indirect steel trade surplus since AISI began tracking the measurement in 1984. The measurement (comprising imports minus exports of steel-containing products by world areas and steel-consuming markets, expressed in metric tons of steel) accounts for virtually all products made with steel, such as automobiles, machine tools, and appliances. According to AISI, this surplus of 1.1 Mt, when compared with the 1986 indirect steel-trade deficit of 8.4 Mt, confirmed that in 1997 U.S. manufacturers were among the world's most competitive producers of high-quality, steel-containing goods. This surplus was followed by 3 years of increasing deficits—1.2 Mt, 4.7 Mt, and 5.8 Mt in 1998, 1999, and 2000, respectively.

World Review

World production of pig iron totaled about 571 Mt, 6.1% greater than that of 1999 (table 10). In Asia, China continued to be the leading producer of pig iron in the world, producing more than 131 Mt, a 4.8% increase from that of 1999. Japan and the United States followed with 81 Mt and 48 Mt, respectively. The Republic of Korea's production increased slightly. Russia and Ukraine were the only major pig iron producers in the Commonwealth of Independent States (CIS). Production in Russia increased by 9% since 1999 and was the highest in the past 5 years. During 2000, Ukrainian production continued a rising 5-year trend. In North America, the only major producer of pig iron was the United States, where production was 3% more than that of 1999. In South America, the only major pig iron producer was Brazil, producing nearly 28 Mt. Germany was the top producer in the EU producing about the same as in 1999. India's production increased by more than 6% of that of 1999.

DRI production worldwide was about 42 Mt, a 9% increase from that of 1999, and a 27% increase compared with that of 1996 (table 10). The leading technology was the Midrex process, followed by the HYL I and the HYL III processes. Because of the demand for charge materials and the growth of thin-slab casting, interest in DRI by steel producers continued to increase. The leading producer was Venezuela, followed by Mexico, India, and Iran (table 10). World capacity for DRI production was estimated to be nearly 52 million metric tons per year (Midrex Direct Reduction Corp., 2000). Additional DRI capacity of nearly 1.4 Mt was under construction in Iran and the Republic of Korea.

World production of crude steel exceeded 845 Mt, a 7.0% increase from the 789 Mt (revised) produced during 1999 (table 11). As in previous years, production varied widely among major regions of the world. Asian countries produced about 38% of the world's steel; the EU, 17%; and North America, 14%. During 2000, China was again the world's leading steel producer, exceeding 127 Mt, a gain of more than 2% compared with that of 1999. In descending order, the leading producers behind China were the United States, Japan, Russia, Germany, and the Republic of Korea. These six countries accounted for more than one-half of the world production. The combined steel production of the seven steel-producing countries in the CIS was over 98 Mt, an increase of nearly 18% compared with that of 1999. Russia and Ukraine remained the top producers, continuing to increase production over recent lows in 1998 (table 11).

Outlook

For 2001, the IISI forecast increasing world steel consumption of about 2.3% from that of 2000 (Steel Times International, 2000). The independent steel research unit, World Steel Dynamics, forecast that global demand for steel products will increase at a rate of 2.6% per year to 2010 (Kakela, 2000, p. 6). According to IISI, apparent consumption in the United States will decrease about 0.1%. Apparent consumption will increase, according to the IISI, in Brazil by 6.3%; the Republic of Korea, 4.7%; China, 7.3%; the EU, 0.4%; the CIS, 1.2%; and other Europe, 5.0%. Consumption will decrease in Japan by 0.7%. The IISI also predicted that by 2005 apparent consumption will increase more than that of 2001 in China, 3.8%; other Europe, 3%; the CIS, 2.8%; the EU, 0.8%; and North America, 0.9%. Consumption will decrease in Japan by 1%.

At the close of 2000, Government and industry economists and steel industry analysts were beginning to suspect that the record-breaking business expansion might be coming to an end. At the time of the Asian financial crisis of 1997-98, the U.S. economy was growing at a rate of about 5% per year and steel demand was very strong. By the end of 2000, the growth rate had declined by nearly one-half and demand for steel had diminished (Sacco, 2000). It was becoming increasingly apparent that the health of the domestic steel industry might improve, not by continuing to rely on antidumping trade laws, but by the consolidation of mills, especially the integrated mills, and even, perhaps, the minimills (Robertson, 2000). Large companies formed by the consolidation of small capitalization companies should be able to reduce overhead, achieve purchasing scale, eliminate unnecessary product duplication, and control pricing better while attracting investors to finance modernization. Only by closing inefficient capacity, reducing costs, adopting the latest steelmaking technology, and improving return on invested capital will these new companies become competitive with foreign mills. The industry would also need to decide whether it wants to produce less raw steel than domestic demand requires and continue to import supplementary quantities of semifinished steel to emphasize downstream product lines (Berry, 2001). To some observers, relinquishing significant raw steelmaking capacity to foreign countries by closing down coke ovens and blast furnaces raises national security concerns.

Minimills continued to improve efficiency and competitive capability, which supports the commonly held view that the EAF will eventually be the primary steel production method in the United States and the world. At least in the United States, blast furnaces will continue to face closure because of environmental restrictions, U.S. steelmakers are increasingly reluctant to make long-term maintenance expenditures on blast furnaces, and the EAF is more energy efficient and pollution free. Minimills cost less to build and operate, are more flexible in satisfying customer requirements, and satisfy the growing demand for recycling. Minimills will increase their efforts to conserve energy, which is about 75% less than for integrated mills. The minimills will increase usage of some form of iron—DRI, pig iron, hot metal—with the scrap charge to improve the quality of the steel they produce to serve broader

Digitized by Google

markets. Thin slab casting in minimills eliminated the need for traditional hot-rolling facilities to reduce slab to hot-rolled sheet. Similarly, newly developing thin-strip casting may produce light-gauge sheet steel without several hot and cold reduction steps. This new technology will reduce the need for capital investment and will enable minimills to enter new markets.

TABLE 5
U.S. EXPORTS OF IRON AND STEEL PRODUCTS 1/

(Thousand metric tons)

	1999	2000
Steel mill products:		
Ingots, blooms, billets, slabs	125	102
Wire rods	63	58
Structural shapes-heavy	376	346
Steel piling	14	25
Plates-cut lengths	371	466
Plates-in coils	207	401
Rails-standard	14	28
Rails-other	10	6
Railroad accessories	12	15
Bars, hot-rolled	343	386
Bars, light-shaped	101	104
Bars, concrete reinforcing	116	117
Bars, cold-finished	99	118
Tool steel	12	9
Pipe and tubing-standard pipe	59	74
Pipe and tubing-oil country goods	142	157
Pipe and tubing-line pipe	173	161
Pipe and tubing-mechanical tubing	5	5
Pipe and tubing-stainless	27	37
Pipe and tubing-nonclassified	293	341
Pipe and tubing-structural	82	116
Pipe for piling	4	3
Wire	149	146
Tin mill products-blackplate	11	5
Tin mill products-tinplate	265	289
Tin mill products-tin-free steel	30	47
Sheets, hot-rolled	337	448
Sheets, cold-rolled	502	638
Sheets, and strip-hot-dip galvanized	252	417
Sheets, and strip-electrogalvanized	199	262
Sheets, and strip-other metallic coated	144	155
Sheets, and strip-electrical	74	60
Strip, hot-rolled	87	102
Strip, cold-rolled	223	278
Total	4,920	5,920
Fabricated steel products:		
Structural shapes-fabricated	263	244
Rails-used	26	33
Railroad products	63	48
Wire rope	13	14
Wire-stranded products	40	41
Wire-other products	18	51
Springs	110	96
Nails and staples	31	28
Fasteners	423	339
Chains and parts	24	27
Grinding balls	19	33
Pipe and tube fittings	32	33
Other 2/	56	61
Total	1,120	1,050
Grand total	6,040	6,970
Cast iron and steel products:		
Cast steel pipe fittings	32	33
Cast iron pipe and fittings	73	65
Cast steel rolls	15	18
Cast grinding balls	17	12
Granules-shot and grit	27	29
Other castings	39	45
Total	203	202

1/ Data are rounded to no more than three significant digits; may not add to totals shown.
2/ Includes shapes-cold formed, sashes and frames, fence and sign post, and architectural and ornamental work, and conduit.

Grand total	549,000 r/	576,000 r/	572,000 r/	576,000 r/	612,000
Of which:					
Pig iron	516,000 r/	540,000 r/	534,000 r/	538,000 r/	571,000
Direct-reduced iron	33,000 r/	36,200 r/	37,800 r/	38,000 r/	41,900

e/ Estimated. p/ Preliminary. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Production is pig iron unless otherwise specified.

3/ Direct-reduced iron is obtained from ore by reduction of oxides to metal without melting.

4/ Table excludes ferroalloy production except where otherwise noted. Table includes data available through August 2, 2001.

5/ In addition to the countries listed, Vietnam has facilities to produce pig iron and may have produced limited quantities during 1996-2000, but output is not reported and available information is inadequate to make reliable estimates of output levels.

6/ Figures reported by State Statistical Bureau that the Chinese Government considers as official statistical data.

7/ Reported figure.

8/ Includes blast furnace ferroalloys.

IRON AND STEEL SCRAP

By Michael D. Fenton

Domestic survey data and tables were prepared by David Gibson, statistical assistant.

Iron and steel scrap is a vital raw material for the production of new steel and cast-iron products. The steelmaking and foundry industries in the United States are highly dependent upon the ready availability of scrap from manufacturing operations and from the recovery of products that are no longer used or needed. The steel industry has been recycling steel scrap for more than 150 years. In 2000, domestic electric-arc-furnace (EAF) steel made primarily from recycled ferrous scrap in about 41 minimills was 47% of the total steel produced. Consistent with international usage and Federal Government policy, the U.S. Geological Survey (USGS) reports all data on iron and steel in metric units, unless otherwise noted.

Steel scrap recycling conserves raw materials, energy, and landfill space. The domestic steel industry recycles millions of metric tons per year of steel cans, automobiles, appliances, construction materials, and other steel products. In 2000, the industry's overall recycling rate was 64% (Steel Recycling Institute, [undated], A few facts about steel—North America's #1 recycled material, accessed May 11, 2001, at URL http://www.recycle-steel.org/fact/main.html). The remelting of scrap requires much less energy than the production of iron and steel products from iron ore. Each year, steel recycling saves the energy equivalent of the electrical power needed for 1 year by approximately one-fifth of the houses in the United States (about 18 million). Consumption of iron and steel scrap by remelting reduces the burden on landfill disposal facilities and prevents the accumulation of abandoned steel products in the environment. Every metric ton of steel recycled saves about 1.3 metric tons (t) of iron ore, 700 kilograms (kg) of coal, and 60 kg of limestone that would be needed to make a ton of steel from new raw materials.

In the United States, the primary source of obsolete steel is the automobile (Steel Recycling Institute, [undated], Recycling scrapped automobiles, accessed June 9, 1999, at URL http://www.recycle-steel.org/cars/autorec.html). Of the ferrous metals used to make a typical 2000 U.S. family vehicle, 45% was recycled metal. About 16,000 car dismantlers and 3,000 scrap processors produced about 12.7 million metric tons (Mt) of iron and steel scrap for recycling in 2000—enough steel to produce over 14 million new cars. The recycling rate of automobile scrap steel exceeded 95% in 2000 compared with 91% in 1999.

The recycling rate of obsolete appliance scrap had increased from 20% in 1988 to 81% in 1997, decreased to 72% in 1998, and rebounded to 84% in 2000. During 2000, more than 2.0 Mt of steel were recovered from recycled appliances (Steel Recycling Institute, [undated], A few facts about steel—North America's #1 recycled material, accessed May 6, 2000, at URL http://www.recycle-steel.org/fact/main.html). The typical appliance consists of about 75% steel, and from 25% to 100% of the steel used in appliances is recycled. The recycling rate of steel cans increased to 61% in 1997 from 15% in 1988, decreased to 56% in 1998, and rebounded to over 58% in 2000. The estimated rate of recycling of structural beams and plates in 2000 was 95% and that of reinforcement bar and other materials was 48%. By 2002, an estimated 25% of all new homes built in the United States will be framed in recycled steel.

Minimills in which EAFs are used consumed greater quantities of direct reduced iron (DRI) to improve steel quality, and integrated steelmakers continued to use small quantities of DRI in blast furnaces as a process coolant. Mills often used a feed mix that has equal proportions of DRI, pig iron, and scrap. Although production in the U.S. steel industry increased during 2000, DRI production decreased by 6.6%.

The U.S. steel industry was adversely affected by the 1997 Asian financial crisis as Asian demand for steel and ferrous scrap declined, Asian currency exchange rates declined, and inexpensive steel became available for export to U.S. markets from excess Asian steel-producing capacity. Domestic steel product manufacturers welcomed inexpensive imports, but domestic steel producers were forced to reduce production and scrap consumption, which led to an oversupply of scrap and a plunge of scrap prices to the lowest levels in decades. By early 1999, the steel-producing and scrap industries were on the rebound owing primarily to resurging Asian economies and increasing steel demand in Asia and the United States.

As 2000 began, steel producers and scrap suppliers were increasingly optimistic that they were on track for a slow but certain recovery to precrisis economic levels. However, to the detriment of these sectors, the U.S. economic expansion—the longest in U.S. history—was showing signs of weakening. Concurrently, prices of electricity and natural gas were increasing significantly, and steel imports, which declined in 1999 below the 1998 level, began to increase again in 2000. Prices for steel products and ferrous scrap again plunged to record levels. Although for relief the U.S. steel industry filed trade cases against allegedly dumped hot-rolled carbon steel from 11 countries, it was becoming clear that a more fundamental problem was that the world and the United States had excess steelmaking capacity (Iron and Steelmaker, 2001; Matthews, 2001). Steelmakers had the capacity to produce 15% more steel than the world market demand in 2000, but were adding capacity at the rate of 2% each year.

Environment

In 1997, the U.S. Department of Energy (DOE) contracted to decommission and decontaminate three uranium enrichment plants at DOE's Oak Ridge, TN, nuclear reservation, which contained an estimated 100,000 t of radioactive metals (Paper, Allied-Industrial, Chemical and Energy Workers Union, [undated], Court finds that energy department plan to recycle radioactive metals from nuclear weapons factories poses great potential for environmental harm, accessed July 7, 1999, at URL http://biz.yahoo.com/prnews/990630/dc_court_e_2.html). DOE arranged to sell 6,000 t of contaminated nickel from a former nuclear weapons plant (American Metal Market, 2000a).

Digitized by Google

The Metals Industry Recycling Coalition, which consists of steel, nickel, zinc, copper and brass interests, lobbied to prevent radioactive-contaminated scrap from reaching the commerce stream. Their concern was that consumers would reject recycled goods made from radioactive scrap even if the level of radiation was deemed to be safe by the Government. At yearend 2000, the DOE issued a memorandum recommending the preparation of a full environmental impact statement on the proposed rulemaking governing the release of radioactive metal. The effect was to delay the release of radioactive metal into the commerce stream.

In addition to the radioactive materials, other potentially hazardous materials used in vehicles and durable goods are entering the recycling system (Wiener, 2001). Mercury switches have been suspected as contributors to high mercury readings in recent electric furnace stack tests. Steel air-bag inflators are sealed units that may deploy and injure employees sorting scrap and working in steel mill melt shops. Also, the propellant in the inflators, sodium azide, can be potentially hazardous to the environment. Substitution of mercury switches with pressure switches by vehicle manufacturers and removal of mercury switches and air bag inflators by dismantlers prior to shredding would ensure that injury to employees and the environment do not occur.

In July 1997, the U.S. Environmental Protection Agency (EPA) revised the National Ambient Air Quality Standards for particulate matter (PM), which met resistance by the steel industry. The EPA reduced the standard for airborne PM from 10 microns to 2.5 microns (U.S. Environmental Protection Agency, 1998). The American Iron and Steel Institute and several other business groups initiated litigation against the EPA, and a three-judge panel of the U.S. Circuit Court of Appeals for the District of Columbia ruled that the agency overstepped its authority by interpreting the 1990 Clean Air Act so loosely that it unlawfully usurped Congress' legislative power. The full appeals court voted in October 1999 against reviewing the panel's decision (New Steel, 1999). Later, in May 2000, the Supreme Court entered the dispute by announcing that they will decide whether antipollution regulations must take the costs of compliance, not just health effects, into account. If the Court rules in favor of such cost-benefit analyses, allegedly unneeded and unfeasible air-quality standards might not be required of the steel industry, among others (Washington Times, 2000a).

Consumption

Domestic data for ferrous scrap were derived from voluntary monthly or annual surveys of U.S. scrap consuming operations by the USGS. About 45% of the known manufacturers of pig iron and raw steel responded to the surveys. Their responses represented about 59% of estimated total scrap consumption by this class of consumers. The remaining 41% of scrap consumption was estimated on the basis of prior reports. For manufacturers of steel castings, iron foundries, and miscellaneous users, about 31% of the surveyed establishments, which represented about 46% of estimated scrap consumption by these consumers, responded to the annual survey. Total consumption for these two classes of consumers was estimated by using statistical methods and prior reports. Actual survey data accounted for about 44% of total estimated scrap consumption by all classes of scrap consumers.

In 2000, brokers, dealers, and other outside sources supplied domestic consumers with 54 Mt of all types of ferrous scrap at an estimated delivered value of more than $5.2 billion and exported 5.8 Mt (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) valued at $1.0 billion (tables 1, 8, 11). In 1999, domestic consumers received 51 Mt of scrap at an estimated delivered value of about $4.8 billion; exports totaled 5.5 Mt valued at $758 million. This represented a tonnage increase during 2000 of nearly 6% for received quantities and over 4% for exported quantities. The total value of received and exported scrap grades increased 13% from that of 1999.

Raw steel production was 101.8 Mt in 2000 compared with 97.4 Mt in 1999 (American Iron and Steel Institute, 2000, p. 75). The shares of raw steel produced by electric and basic oxygen furnaces were 47% and 53%, respectively; EAF production increased slightly during 2000. In 2000, continuous cast steel production represented 96% of total raw steel production, as it had in 1999. Raw steel production capability was 118 Mt compared with 116 Mt in 1999.

Steel mills accounted for 84% of all scrap received from brokers, dealers, and other outside sources; iron foundries and miscellaneous users received 14%; and steel foundries received 2% (table 2). Apparent total domestic consumption of ferrous scrap was 54 Mt of net receipts (total receipts minus shipments) and 20 Mt of home scrap (table 1). Stocks of ferrous scrap at consumers' plants decreased by nearly 4% to 5.3 Mt (table 1). Total domestic consumption was about 74 Mt, a 4% increase since 1999 (table 1). The total market for U.S.-produced scrap (net receipts plus exports minus imports) was 56.5 Mt compared with 53.3 Mt in 1999. Feedstock used in electric furnaces by all iron and steel product manufacturers comprised scrap, 91%; pig iron, 5.3%; and DRI, 3.4% (table 4). Consumption of DRI was 11% greater than that of 1999.

Net shipments of all grades of steel mill products were 98.9 Mt, which was an increase of 2.7% from the 96.3 Mt shipped in 1999 (American Iron and Steel Institute, 2000, p. 27). Imports of steel mill products increased to 34.4 Mt from 32.4 Mt in 1999. Exports of steel mill products increased to 5.9 Mt from 4.9 Mt in 1999 (American Iron and Steel Institute, 2000, p. 45). The U.S. apparent supply of steel mill products increased to 120 Mt from 116 Mt in 1999. As a share of the U.S. market, imports of steel mill products increased to 29% from 28% in 1999. Pig iron production increased to 47.9 Mt from 46.3 Mt in 1999 (American Iron and Steel Institute, 2000, p. 80). As reported by the U.S. Census Bureau, iron castings shipments totaled an estimated 9.9 Mt for 1999 and 9.9 Mt (revised) for 1998. Steel castings shipments (including investment castings) totaled 1.2 Mt in 1999, the same as in 1998.

Transportation

In June 1999, the acquisition of Conrail, Inc by CSX Transportation, Inc. (42%) and Norfolk Southern Corp. (58%) reduced the number of large rail carriers from 3 to 2 in 23 States east of the Mississippi River, the District of Columbia, Quebec, and Ontario. The railroad system is the main form of transportation of ferrous scrap in the United States. A significant part of the industry experienced considerable deterioration of service, such as train backups, routing problems, lost cars and billing, erroneous information given to shippers, car unavailability, and mistakenly routed shipments.

Digitized by Google

These problems were based, for the most part, on the railroads' difficulty in integrating the computer systems of the merged railroads. All of this resulted in canceled contracts, smaller orders, and increased costs (American Metal Market, 1999, 2000b). One year later, the general opinion was that the railroads are performing much better (Robertson, 2000). The railroads invested in new track capacity in the Midwest, new terminal capacity in Buffalo, NY, and improvements at railyards throughout the Northeast and the Midwest. They also installed improved computer systems while working closely with shippers to solve delivery problems.

The Surface Transportation Board of the Federal Government ordered in March a moratorium on new consolidations in the railroad industry while it develops new rules for mergers. It was concerned about problems for shippers resulting from recent railroad mergers (Washington Times, 2000b). The steel industry, among others, expressed its opposition to more railroad consolidation because it no longer has an affordable option to choose truck transportation over rail transportation, given recent fuel price increases (American Metal Market, 2000c).

Prices

The average composite delivered price per metric ton of No. 1 heavy-melting steel scrap, calculated from prices per long ton published monthly by American Metal Market, was $95.88. The price ranged from a high of $120.06 in January to a low of $77.36 in December (table 8). The average composite delivered price per ton of No. 1 heavy-melting steel scrap, calculated from prices per long ton published weekly in Iron Age Scrap Price Bulletin, was $92.61; the price had ranged from a high of $112.07 in January to a low of $73.27 in November.

On the basis of weekly quotations by Iron Age Scrap Price Bulletin for 18-8 (18% chromium, 8% nickel) stainless steel scrap (bundles and solids) delivered to consumers in the Pittsburgh, PA, area, the average price increased by 32% to $823 per metric ton from $624 in 1999.

The unit value of total ferrous scrap exports (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) increased by about 30% to about $174 per metric ton compared with that of 1999 (table 11). The unit value of total imports, about $85 per ton, was about 18% less than that of 1999 (table 14).

Foreign Trade

Foreign trade valuation continued to be reported on a free-alongside-ship (f.a.s.) basis for exports and on a Customs value basis for imports. In 2000, the U.S. trade surplus for all classes of ferrous scrap (including used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) was 2.2 Mt valued at $597 million (U.S. Census Bureau, unpub. data, 2000). This represented an increase of 42% in quantity and 82% in value compared with the 1999 surpluses of 1.5 Mt and $328 million.

Total U.S. exports of carbon steel and cast-iron scrap (including reexports and excluding used rails for rerolling and other uses; ships, boats, and other vessels for scrapping; stainless steel; and alloy steel) went to 55 countries (1 less than during 1999) and totaled 4.5 Mt (a 4% decrease) valued at $526 million (an 11% increase) for an average of $116 per ton (U.S. Census Bureau, unpub. data, 2000). The largest tonnages went to the Republic of Korea, 1.24 million; Canada, 1.04 million; Mexico, 792,000; China, 773,000; and Taiwan, 205,000. These countries received 90% of the total quantity valued at $451 million, which was 86% of the total value.

Total U.S. exports of stainless steel scrap, including reexports, went to 43 countries (12 more than in 1999) and consisted of 470,000 t (an 80% increase) valued at $311 million (a 105% increase) for an average of $661 per metric ton (a 14% increase) (U.S. Census Bureau, unpub. data, 2000). The largest tonnages went to the Republic of Korea, 181,000; Taiwan, 80,000; Canada, 47,000; Japan, 46,000; and China, 24,000. These countries received 80% of the total quantity valued at $248 million, which also was 80% of the total value.

U.S. exports of alloy steel scrap (including reexports and excluding stainless steel) were shipped to 46 countries (1 more than in 1999) and consisted of 815,000 t (a 46% increase) valued at $169 million (a 47% increase) for an average of $207 per metric ton (a 1% increase) (U.S. Census Bureau, unpub. data, 2000). The largest tonnages went to China, 295,000; Mexico, 214,000; and Canada, 202,000. These countries received 87% of the total quantity valued at $138 million, which was 82% of the total value.

World Review

Iron and steel scrap is an important raw material for the steel and foundry industries. Because scrap comes from such sources as old buildings, industrial machinery, discarded cars and consumer durables, and manufacturing operations, the relatively mature industrialized economies are generally the main exporters of scrap to lesser developed steelmaking countries.

Germany was the leading exporting country of iron and steel scrap in 1999 (International Iron and Steel Institute, 2000, p. 102), followed by Russia, the United States, Ukraine, Japan, France, the United Kingdom, and Canada. The five most significant importing nations were, in decreasing order of importance, Turkey, the Republic of Korea, Spain, Italy, and the United States (International Iron and Steel Institute, 2000, p. 104).

Outlook

As 2000 opened, the longest economic expansion in U.S. history began its 105th month, and the economies of Asia, Europe, and Latin America were improving. The expectation was for continued strong domestic economic growth and strong demand for steel products and ferrous scrap. In October 2000, the International Iron and Steel Institute forecast an increase in world steel consumption of 5.8% during 2000 and 2.3% during 2001 for a total of 769 Mt in 2001 (International Iron and Steel Institute, [undated], Short and medium term outlook for steel demand, accessed June 5, 2000, at URL http://www.worldsteel.org/ trends_indicators/demand.html). About 15% of the 1999-2000 increase is accounted for by estimates for China. It is predicted that China will soon be consuming more steel than either the European Union (EU) or the countries of the North American Free Trade Agreement. Even without the Chinese contribution to the total, world steel demand is forecast to grow by 35 Mt in 2000 and 7 Mt in 2001, and 43 Mt through 2005. Consumption will increase during 2001 in China, 7.3%; the Commonwealth of Independent States,

Digitized by Google

1.2%; the EU, 0.4%; and the Republic of Korea, 4.7%; while the United States and Japan may experience slight declines of less than 1% each. However, by the fourth quarter 2000, the U.S. economy began to soften, as did demand for steel and scrap. Prices for these commodities declined as inventories grew, putting the steel sector back into a depressed state similar to that experienced during the Asian financial crisis 3 years earlier. Imports of low-price steel and scrap again brought calls for relief from unfair dumping. Although the industry was hoping for relief on the imports issue, by yearend 2000 the realization was growing that the problem of excess U.S. uneconomic steelmaking capacity would need a solution.

The United States is the top consumer of ferrous scrap while holding the world's largest stockpile of ferrous scrap resources. The United States has had sufficient scrap resources to satisfy domestic steelmaking needs while being able to export significant scrap quantities to newly emerging economies with developing steelmaking capacities. Steelmaking by the EAF in the minimill will continue to grow in the United States because of its capital and operating cost advantages relative to those of the blast furnace and basic oxygen furance, and it is environmentally cleaner (Darrell Hassler, November 11, 1998, Scrap trade pins hopes on minimills, accessed June 11, 1999, at URL http://www.amm.com/ref/hot/fersc98a.htm#3). In fact, the ratio of EAF steelmaking to BOF steel production has been forecast to increase to 60% from the current 47% (TexReport, 2001).

Continuing expansion of EAF mills in the eastern United States has been absorbing available local scrap resources, thereby causing east coast exports to Europe and Turkey to decline. Demand for scrap in the western United States has not been increasing at a similar pace to that in the eastern United States, and west coast scrap export is expected to increase to satisfy the emerging demand of China, which may displace the Republic of Korea as the largest overseas scrap market.

Totals, all manufacturing types:						
Ferrous scrap consumption		71,000	73,000	73,000	71,000	74,000
Pig iron consumption		52,000	52,000	50,000	49,000	50,000
Direct-reduced iron consumption		1,300	1,300	1,300	2,200	2,300
Net receipts of ferrous scrap 3/		50,000	52,000	53,000	51,000	54,000
Home scrap production 4/		20,000	20,000	20,000	19,000	20,000
Ending stocks, December 31:						
Ferrous scrap at consumer plants		5,200	5,500	5,200	5,500	5,300
Pig iron at consumer and supplier plants		600	510	560	720	800
Direct-reduced iron at consumer plants		270	160	280	310	290
Exports: 6/						
Ferrous scrap (includes tinplate and terneplate) 7/		8,440	8,930	5,570	5,520	5,760
Value	thousands	$1,340,000	$1,350,000	$805,000	$738,000	$1,000,000
Pig iron (all grades)		58	86	87	83	72
Value	thousands	$8,320	$12,300	$11,700	$11,100	$9,620
Direct-reduced iron (steelmaking grade)		3	8	5	3	2
Value	thousands	$304	$852	$487	$302	$241
Imports for consumption: 6/						
Ferrous scrap (includes tinplate and terneplate) 7/		2,600	2,870	3,060	3,670	3,350
Value	thousands	$342,000	$384,000	$402,000	$383,000	$385,000
Pig iron (all grades)		2,660	3,150	5,150	4,990	4,970
Value	thousands	$411,000	$465,000	$722,000	$527,000	$601,000
Direct-reduced iron (steelmaking grade)		1,050	987	939	950	1,090
Value	thousands	$136,000	$127,000	$118,000	$86,500	$119,000

1/ Data are rounded to no more than two significant digits, except trade data, which are rounded to no more than three significant digits; may not add to totals shown.

2/ Includes manufacturers of raw steel that also produce steel castings.

3/ Net receipts of scrap is defined as receipts from brokers, dealers, and other outside sources, plus receipts from other own-company plants minus shipments.

4/ Home scrap production includes recirculating scrap that results from current operations and obsolete home scrap.

5/ Some consumers in the "Manufacturers of steel castings" category also produce iron castings; some consumers in the "Iron foundries and miscellaneous users" category also produce steel castings.

6/ Data from U.S. Census Bureau. Export valuation is free-alongside-ship (f.a.s.) value, and import valuation is Customs value.

7/ Excludes used rails for rerolling and other uses and ships, boats and other vessels for scrapping.

California, Oregon, Washington	2,600	W	310	(5/)	(6/)	2,900
Total	4,800	W	850	(6/)	5	5,700
Grand total	53,000	2,800	19,000	280	2,200	74,000

W Withheld to avoid disclosing company proprietary data. -- Zero.

1/ Supply available for consumption is a net figure computed by adding production to receipts and deducting scrap shipped during the year. The difference in stock levels at the beginning and end of the year is not taken into consideration.

2/ Data are rounded to no more than two significant digits; may not add to totals shown.

3/ Obsolete scrap includes ingot molds, stools and scrap from old equipment, buildings, etc.

4/ Includes scrap shipped, transferred, or otherwise disposed of during the year.

5/ Less than 1/2 unit.

6/ Withheld to avoid disclosing company proprietary data; included in "Total" or "Grand total."

IRON ORE

By William S. Kirk

Domestic survey data and tables were prepared by Heather A. Geissler, statistical assistant, and the world production table was prepared by Linder Roberts, international data coordinator.

Domestic production of iron ore in 2000 increased by 9%, reflecting an increase in steel production with the attendant increase in pig iron production. Similarly, world iron ore output rose reflecting higher levels of steel and pig iron production. There were major acquisitions in the iron ore industry. Iron ore prices increased.

Iron ore is essential to the economy and national security of the United States. As the basic raw material from which iron and steel are made, its supply is critical to any industrial country. Scrap is used as a supplement in steelmaking but is limited as a major feed material because the supply of high-quality scrap is limited. However, alternatives, such as direct reduced iron (DRI), were available, and their use is growing. In 2000, the steel industry accounted for more than 98.5% of iron ore consumption.

Iron ore is a mineral substance which, when heated in the presence of a reductant, will yield metallic iron. It almost always consists of iron oxides, the primary forms of which are magnetite (Fe_3O_4) and hematite (Fe_2O_3). Taconite, the principal iron ore mined in the United States, has a low (20% to 30%) Fe content and is found in hard, fine-grained, banded iron formations.

Production

Following a year marked by reduced demand for iron ore, U.S. iron ore production in 2000 reached its highest level since 1981, 63.0 million metric tons (Mt).

The nine taconite mining operations in Michigan and Minnesota accounted for virtually all domestic iron ore production. Seven of these operations were on the Mesabi Iron Range in northeastern Minnesota: EVTAC Mining LLC, Hibbing Taconite Co., Inland Steel Mining Co., LTV Steel Mining Co., National Steel Pellet Co., Northshore Mining Co., and the US Steel Group of USX Corp. (Minntac). The two taconite operations on the Marquette Iron Range in the Upper Peninsula of Michigan were the Empire and the Tilden Mines.

U.S. production data for iron ore are developed by the U.S. Geological Survey (USGS) by means of the annual "Iron Ore" survey, which provided 100% of total production shown in tables 1 through 4. This information is supplemented by employment data, mine inspection reports, and information from consumers. The American Iron Ore Association (AIOA) provided data on ore shipments from loading docks on the upper Great Lakes, as well as receipts at transfer docks and furnace yards nationwide. The dock and steel plant data were compiled jointly by AIOA and the American Iron and Steel Institute (AISI).

Iron ore was produced by 13 companies. One other company did not produce ore, but shipped it from stockpiles. The nine taconite producers in Michigan and Minnesota accounted for 99% of domestic production. The producing companies operated 13 mining operations, 10 iron ore concentration plants, and 10 pelletizing plants. Of the two iron ore producers that did not produce pellets, one produced iron ore as a byproduct of gold mining, and the others produced direct-shipping ore, which requires minimal processing. Of the 13 mining operations, 12 were open pit and 1 was underground. Virtually all ore was concentrated before shipment, and 99% was pelletized. In 2000, combined United States and Canadian production represented 9% of the world output of usable ore in terms of metal content. Trends in world mine production since 1996 are shown on a country basis in table 17.

Domestic iron ore supply (production minus exports) satisfied 75% of domestic demand in 2000, compared with an average of 70% from 1990 through 2000. Domestic iron ore production, at 63 Mt, increased by 9% from that of 1999. Productivity in the Lake Superior District, in terms of thousands of tons of usable

Iron Ore in the 20th Century

From well before 1900 and into 2000 virtually all iron ore has been used to make steel, so the iron ore industry's fortunes were and continued to be inextricably linked to those of the steel industry. In 1904, the United States was the world's largest iron ore producer, accounting for about 60% of total world output of 46 million metric tons (Mt). Despite this, the United States was already a net importer of iron ore, if only by a small margin. After domestic production peaked at 127 Mt during World War II, it became apparent that U.S. reserves of high-grade ore would be seriously depleted by the 1950s. It was in this decade that production of high-grade pelletized concentrate began. Despite the need for much more processing, compared with the direct shipping ores of the past, the use of pellets made blast furnaces much more productive.

By the end of the 20th century, world iron ore production had grown to more than 1 billion tons per year. In the United States, however, production averaged about 60 million tons per year (Mt/yr) and consumption averaged 77 Mt/yr. The United States ranked as the sixth largest producing nation and accounted for only 6% of world production. Globally, the proportion of ore production that was exported continued to grow, reaching almost 45%. Australia and Brazil increasingly dominated that export market, capturing almost 70%. The end of the 20th century saw a wave of consolidation in the iron ore industry as producers strove to reduce production costs and become more competitive.

Digitized by Google

ore produced per worker in 2000, was 9.3, an 8% increase from that of 1999. Low-grade ores of the taconite type mined in Michigan and Minnesota accounted for 99% of total usable ore production. U.S. production of pellets totaled 62.4 Mt. The average Fe content of usable ore produced was 62.9%. Fluxed pellets' share of total pellet production was 60% in 2000.

Michigan.—Michigan accounted for 23.8% of the output of usable ore in 2000. Pellets accounted for 99% of total production.

Minnesota.—Minnesota produced 76.1% of the national output of usable ore in 2000. All the State's production came from open pit mines on the Mesabi Range.

LTV Steel Co., Inc., a subsidiary of The LTV Corp., on May 24, announced its intention to close permanently the operations of LTV Steel Mining Co. (LTVSMC). LTVSMC was located at Hoyt Lakes, MN, employed approximately 1,400 people, and produced about 7 Mt of pellets in 1999. LTV Steel stated that its blast furnaces were experiencing lower levels of productivity and higher costs as a result of operating problems related to poor taconite pellet quality. The poor quality pellet was the result of deteriorating ore quality and the obsolete shaft furnaces used in the pelletizing plant. LTVSMC operated the only remaining shaft furnaces in the North American taconite pellet industry. These maintenance-intensive furnaces were not competitive with modern straight grate or grate kiln furnaces, which produce better quality pellets at lower cost. Replacement of the shaft furnaces and other related changes would require investments of about $500 million within 3 years, and a total investment of about $700 million in the next 10 years. The company said that such an investment could not be justified and would not resolve the problems of poor quality ore reserves (Kirk, 2000a).

Another major problem at the mine was the high stripping ratio. Stripping is the removal of layers of soil and waste rock that cover the ore. The more overburden that must be stripped to expose the crude ore, the higher the stripping ratio and, consequently, the higher the production costs. The iron formation on the Mesabi Range dips at an angle of about 8 degrees. Mining must follow the iron formation down dip, and as it proceeds, the overburden becomes thicker. Because LTVSMC was the oldest continuously operating taconite mining operation on the Minnesota Iron Range, and had some of the deepest pits, it had considerably more stripping to do than the other producers (Kirk, 2000a).

Minntac closed one of its agglomerating lines on November 5th for the remainder of the year. National Steel Pellet Co. announced that it would lay off 22 employees at the end of the year. The closings were attributed to low iron ore demand that was the result of high levels of steel imports (Lee Bloomquist, Duluth News Tribune, November 7, 2000, Minntac layoffs delayed—Agreement prevents cuts until year's end, accessed November 7, 2000, at URL http://www.duluthnews.com/today/dnt/tac.htm; Lee Bloomquist, Duluth News Tribune, December 8, 2000, Keewatin taconite plant to lay off 22, accessed December 8, 2000, at URL http://www.duluthnews.com/today/dnt/nat.htm).

Missouri.—Pea Ridge Iron Ore Co. produced iron oxide powder at its mining complex near Sullivan. The company has the only active underground iron ore mine in the country. In January 1991, the company ceased pellet production and began concentrating on specialty iron oxide products, which had formerly been coproducts.

Consumption

Data on consumption and stocks of iron ore and iron ore agglomerates (pellets and sinter) at iron and steel plants were provided by the AIOA. Data on consumption of iron ore for nonsteel end uses were compiled from information gathered from USGS surveys. Domestic iron ore consumption, responding to increased steel production, rose 2%, to 76 Mt. Stocks and net imports increased.

The number of blast furnaces in operation during the year ranged from 33 to 36. Consumption of iron ore, including agglomerates reported to the AISI by integrated producers of iron and steel, totaled 73 Mt. This included 61.8 Mt of pellets; 10.8 Mt of sinter, briquettes, etc.; and 0.4 Mt of natural coarse ore. Of the ore consumed, 82% was of domestic origin, 9% came from Canada, and 9% came from other countries. Other materials consumed in sintering plants included mill scale, flue dust, limestone and dolomite, slag and slag scrap, and coke breeze. Other iron-bearing materials charged to blast furnaces included mill scale, slag scrap, and steel-furnace slag.

The four consumption numbers in this annual review are listed in tables 1, 6, 7, and 8. The following explains why more than one consumption number is used and how each of them is derived. The first consumption number (76.5 Mt in 2000) is in table 1 and is the sum of the quantity of ore consumed by form as reported by the AISI (American Iron and Steel Institute, 2000, p. 84) and the quantities of ore consumed in DRI production and ore consumed in nonsteel uses, as reported to the USGS; the AISI number is reported in short tons and is converted to metric tons. The second consumption number (70.7 Mt in 2000) is in table 6 and is the quantity of ore consumed at U.S. iron and steel plants by originating area, as reported by the AIOA; the number has been converted from long tons, as it appears in the AIOA annual report, to metric tons (American Iron Ore Association, 2000, p. 42). The third consumption number (73.0 Mt in 2000) is in table 7 and is the quantity of ore consumed in U.S. iron and steel plants by type of ore as reported by the AISI; the number has been converted from short tons, as it is listed in the AISI annual report, to metric tons (American Iron and Steel Institute, 2000, table 32). The fourth consumption number (74.1 Mt in 2000) is in table 8 and is the sum of the AIOA number for consumption at United States Iron and Steel plants (American Iron Ore Association, 2000, p. 46, 47) and two other numbers; these are the quantities of ore consumed in DRI production (2.3 Mt in 2000) and nonsteel uses (1.2 Mt in 2000) as reported to the USGS. In summary, iron ore consumption for steelmaking is calculated by the AIOA and the AISI using different methods. To obtain total domestic iron ore consumption, iron ore consumption for other end uses must be added to AIOA and AISI reported consumption, thereby generating four consumption numbers.

Ispat International NV planned to install electric arc furnaces at its Inland Works in East Chicago to replace the No. 2 oxygen steelmaking shop there. Blast furnaces nos. 5 and 6 were nearing the end of their working lives, but were not to be replaced. Instead, Ispat planned to put in two electric furnaces with a combined capacity of about 3 million metric tons per year (Mt/yr), about the same as the existing facilities (Metal Bulletin, 2000q).

Prices

Most iron ore prices are negotiated between buyer and seller. In 2000, 79% of domestic ore was produced by captive mines (mines producing for company-owned blast furnaces) and, therefore, did not reach the open market and cannot be said to have a price. Slightly less than 20% of domestic production came from mines wholly or partly owned by Cleveland-Cliffs Inc. (Cliffs). Prices for that ore were unavailable. Prices may be available for the less than 1% of ore from mines owned by steel companies and Cliffs, but those prices would be representative of only a tiny portion of domestic production.

The average free-on-board mine value of usable ore shipped in 2000 was $25.57 per metric ton, slightly lower than that of 1999. This average value should approximate the average commercial selling price less the cost of mine-to-market transportation.

International iron ore prices rose in 2000. The price for Hamersley Iron Ore Pty. Ltd. and Mount Newman Mining Co. Pty. Ltd. fine ores for fiscal year 2000 (April 1, 2000, to March 31, 2001) in the Japanese market was 27.35 cents per 1% Fe per long ton unit, up 4.4% compared with that of 1999 (Duisenberg, 2001, p. 46). The price for lump ore was settled at 36.26 cents per 1% Fe per long ton unit, an increase of 5.8 % compared with that of 1999. The lump ore to fine ore premium for Australian ore sold to Japan, increased from 8.2 in 1999 to 9.1 cents per 1% Fe per long ton unit. There were similar price percentage decreases in Europe. Iron ore prices have declined over the long term as well. The price of Carajás fines, a grade of ore produced by Companhia Vale do Rio Doce (CVRD) and sold to Europe, when denominated in U.S. dollars and adjusted for inflation using the U.S. Consumer Price Index for All Urban Consumers, fell by 33% between 1990 and 2000.

Transportation

Almost no iron ore is consumed near its source; most ores must be transported, often great distances. Nearly all iron ore leaves the mine by rail, after which much of it is transferred to ships. In the United States, a much larger proportion of ore is moved by water than in other countries because of the proximity of the mines to the Great Lakes, which offer low-cost transportation. No taconite mine is more than about 160 kilometers (km) from Lake Superior or Lake Michigan, and most are much closer. In 2000, 47.5 Mt of ore was moved on the Great Lakes, the equivalent of about 75% of domestic production. Iron ore constituted 47% of U.S.-flag cargoes, more than twice that of stone and gypsum, the next largest dry bulk material category shipped. Excluding transshipments, U.S.-flag carriers moved 53 Mt of iron ore in 2000.

Iron ore plays a more important role in Great Lakes shipping than is readily apparent. Significant quanities of coal and stone move via the Great Lakes, but they are generally backhaul cargoes. When a laker (ore carrier) moves an iron ore cargo to a steel mill, it often carries a stone or coal cargo on the way back to the iron ore ports of Lake Superior. Without iron ore to fill one leg of the voyage, freight rates would increase so much that railroads would capture much of these markets (Lake Carriers Association, oral commun., July 12, 2001).

The U.S. Congress passed and the President signed a bill providing funding for a new icebreaker for the Great Lakes. The $110 million contract for building the ship was expected to be let in July 2001, with the vessel scheduled to be working by 2005. The current icebreaker, the 56-year old Mackinaw, is well beyond its designed service life and is scheduled to be decommissioned in 2006 (Steve Kuchera, Duluth News Tribune, July 1, 2000, Senate funds new icebreaker—$110 million to go to Mackinaw replacement—U.S. Coast Guard's Great Lakes icebreaking capability replacement project, accessed July 5, 2000, at URL http://www.duluthnews.com/news/day4/dnt/local/ship.htm; Lake Carriers Association, oral commun., March 12, 2001).

The near drought conditions that have been causing low water levels in the Great Lakes since 1998 persisted through 2000. Lake Superior began the year at about 20 centimeters (cm) below the long-term average (LTA) and ended at about 38 cm below the LTA. The largest cargo shipped from Two Harbors in 2000 was 58,716 metric tons (t) compared with 62,559 t in 1998, an 8% drop. The average cargo shipped from Two Harbors for the same period fell by 7% (Lake Carriers Association, 2000).

The greatest financial loss caused by the low water levels was suffered by the shipping companies that transport iron ore on the Great Lakes. These companies enter into contracts with steelmakers to move a given quantity of ore at a certain price. Because of the low water levels, the ore boats must carry lighter loads to avoid running aground, so it takes more trips to carry a given quantity of ore. The shipping companies have not raised their rates to pass higher costs on to the steel companies because most of the steel companies are having financial troubles of their own.

Foreign Trade

Net imports, as usual responding strongly to the increase in consumption, rose 17%. U.S. exports of iron ore were less than 1% higher than those of 1999 (tables 9-15). U.S. net import reliance as a percent of apparent consumption of iron ore was 10% in 2000. Almost all exports consisted of pellets shipped via the Great Lakes to Canadian steel companies, which are partners in U.S. taconite projects in Michigan and Minnesota. U.S. imports of iron ore at 15.7 Mt, were 10% higher than those of 1999. Net imports, which averaged 11 Mt from 1989 through 2000, were 9.5 Mt in 2000. This was equivalent to 14% of U.S. ore consumption. Canada's share of U.S. imports was 51%; Brazil's was 39%.

World Review

The year 2000 was characterized as one in which major consolidation in the iron ore industry began. (See section below on Mergers and Acquisitions.)

Production.—World iron ore production was 1.1 Mt, a 4% increase compared with that of 1999 (table 17). Although iron ore production was widely distributed, taking place in about 48 countries, the bulk of world production came from just a few countries. The five largest producers, in decreasing order of production of gross weight of ore, were China, Brazil, Australia, Russia, and India. The United States and Canada were 6th and 8th. The top five accounted for 70% of world production.

China was the largest producer in gross weight of ore produced, but because its ore was of such low grade, the country's output ranked well below Australia's and Brazil's output in Fe content. Of the largest producing countries, India

Digitized by Google

experienced the highest growth, increasing 7% over production in 1999.

Consumption.—World iron ore consumption, as indicated by the production of pig iron, DRI, and crude steel, reached record high levels. These are the chief indicators of iron ore consumption, with pig iron and DRI production being the more direct indicators. World pig iron production increased by 6% to 572 Mt. Asia's share of world pig iron production has consistently increased, rising from 35% in 1990 to 47% in 2000. In the same period, Europe's share fell from 24% to 21% and the former Soviet Union's share fell from 21% to 13%. DRI production increased by 12%, reaching 43 Mt in 2000.

World crude steel production grew by 7.4%, the largest such gain since 1973. The largest gains in production were in the countries of the former Soviet Union (14.4%), followed in decreasing order by Asia (7.5%), Western Europe (5.8%), and North America (3.9%). Six countries accounted for 57% of world crude steel production. From 1990 through 2000, Asia's share of world crude steel production rose from 31% to 39%. North America's rose from 14% to 16%. Europe's share fell from 28% to 25%. For the rest of the world as a whole, production share fell from 27% to 20%.
